10	,,	M. 19	Son of No. 9.	—	Both clavicles kinked, but the two halves firmly united.	—	Large depression in lower half of sternum.
11	,,	M. 14	Son of No. 9.	—	Left clavicle very arched and prominent. Right side sternal part 2¼ inches overriding the acromial end, which is 1¼ inches; united by ligament.	—	Large transverse process of seventh cervical vertebra.
12	,	F. 12	Daughter of No. 9.	—	Left side normal. Right side sternal portion 2 inches overlapping the acromial, 1¼ inches.	—	Large transverse process of seventh cervical vertebra; flat feet.
13		F. 8	Daughter of No. 9.	Large head.	Sternal portions small; left side 1¼ inches, right side ¾ inch. Acromial portions absent. On left side x rays show a faint shadow between the acromion and coracoid. Sterno-mastoid muscle normal. Anterior part of deltoid and clavicular head of pectoralis major absent.	Small	Large transverse process of seventh cervical vertebra; large first (terminal?) phalanges.
14	,,	M. 7	Son of No. 9.	—	On left side the clavicle is notched, but the two halves firmly united. Right side, sternal part, 1⅜ inches; acromial part, 1½ inches; united end to end by strong ligament.		Transverse process of seventh cervical vertebra very prominent.

No.	Name of reporter.	Sex and age.	Family history.	Head.	Clavicles.	Aspect and intelligence.	Remarks.
15	Voisin and de Lepinay.	F. 6	Parents died from tuberculosis.	Head brachycephalic and bossed; both fontanelles, the metopic, and sagittal sutures open.	Left represented by a piece 2·5 cm. long at junction of inner and middle thirds; attached to sternum by ligament and extends outwards to the first rib, not to the acromion. Right sternal end 1·5 cm. long, the thickness of a crow quill.	Height, 1·18 metres; thin, intelligent.	Kyphosis and scoliosis, deformed chest. Bony palate not joined, but the soft parts bridge across the deficiency. Congenital dislocation of the radii backwards. The thumb longer and the fingers shorter than normal with enlarged ends. Genu valgum and flat feet; teeth irregular.
16	Morand.	—	Only survived a day.	—	Absence of clavicles, sternum, and costal cartilages.	—	—
17	Martin.	M. 30	Father and brothers had the same deformity.	—	Inner end present on one side (which not stated), the bone being only three-quarters the length of its fellow. A nodule of bone was developed in connexion with the coracoid.	—	—
18	Stahmann.	M. 9	—	—	Left clavicle absent and replaced by fibrous or cartilaginous tissue; right normal.	Normal.	Unaware of his defect.
19	Gegenbaur.	F. 56	Information not obtained of the parents of the mother and her two husbands.	—	Left side, sternal end 5 cm., right side, 6 cm. Sterno-mastoids attached to fragments, deltoids to acromion. Clavicular head of pectorals only slightly developed.	—	No other deformities.
20	,,	M. 36	Son of No. 19 by first husband.	—	Acromial portions absent on both sides. Sternal end 7 cm. left side and 6 cm. right side.	Small, 1·52 metres; fat.	Bent xyphisternum.
21	,,	M. 14	Son of No. 19 by second husband.	—	Sternal fragments 6 cm. left side and 5 cm. on right side. Acromial end joined by pseudarthrosis to the sternal end on the left side, absent on the right side.	Small, 1·31 metres.	—
22	,,	F. 22	Daughter of No. 19 by second husband, and had a normal child.	—	Sternal fragments, left 6 cm., right 4 cm. Acromial fragments, left 4 cm., right 5 cm.	—	—
23	Niemeyer.	M.	—	—	Total absence of left clavicle.	—	Scoliosis.
24	Scheuthauer.	M. 56	—	Skull thin and porous, Wormian bones present; fontanelles and sutures still open; head bossing, and an angle at the spheno-occipital synchondrosis.	Rudiments of the sternal ends with a fibrous band passing from the sternum to the glenoid cavity, to which were attached the sterno-mastoid, great pectoral, subclavius, and deltoid muscles. A small process 1 inch long was developed above the glenoid. The subclavius muscle was very large.	Small.	Atrophy of facial bones, malformed nasal bones; thorax flat. Died from phthisis; old hæmorrhage in frontal lobe.
25	,,	M. Old	—	Vault of skull compact; fontanelles and sutures open.	Small sternal nodules on both sides.	—	Atrophy of the facial bones. Skeleton in the Museum of Anatomy and Pathology, Vienna.
26	Dowse.	F. 15	Mother and six sisters well; no information as to father.	Large head; frontal and parietal bosses, with a mesial depression extending from the frontal region.	Only acromial ends present, slightly better developed on the right side.	Fat; normal intelligence.	Teeth irregular and ill developed; poorly shaped feet and broad sternum.
27	Kapler.	F. 16	Father and three sisters have congenital talipes varus; one sister dead.	Large head (figured in "Le Traité des Maladies Chirugicales Congenitales," Kirmisson, Paris, Masson, 1898, p. 497).	Sternal fragments only; right 1½ cm., left 4 cm. by ½ cm. broad; no fibrous continuation. Only one head of the sterno-mastoid muscle is present on the right. Other muscles normal.	Small and fat; 1·29 metres; intelligent.	Talipes varus congenital; great depression of sternum. Phthisical.
28	Hamilton.	$\frac{M}{F}$	—	Fontanelles and sutures abnormally large.	Total absence of both clavicles.	—	Died when 6 months old from marasmus. Numerous congenital dislocations.
29	Guzoni degli Ancaroni.	F. 60	Father and mother dead; well formed.	—	Sternal ends present; left 8 cm., right 5½ cm.; fibrous cord on left side.	Small, 1·47 metres.	Dorsal kyphosis; large intercostal spaces; low sterno-clavicular articulations. Had three abortions at the third month; no cause.

No.	Name of reporter.	Sex and age.	Family history.	Head.	Clavicles.	Aspect and intelligence.	Remarks.
30	Gibert.	F. 15	—	Large head, vault nearly all membranous.	Absent on both sides.	—	Nose crooked, face small. Died from acute osteomyelitis.
31	Todd.	—	—	—	Sternal and acromial fragments ununited on both sides.	—	Condition noted post mortem. Photograph.
32	Van den Bussche.	—	—	—	Sternal ends short; acromial ends absent on both sides.	—	Two illustrations.
33	Hultkrantz.	F. 46	—	Forehead large, median furrow; anterior and posterior fontanelles open.	Sternal ends; left 5 cm., right 4 cm. Prolongations passing out to the coracoid process. Acromial ends absent.	—	Teeth bad, dentition irregular; palate pointed.
34	,,	F. 28	—	Broad head; posterior fontanelle open.	Left side, inner end 6·4 cm., outer 5 cm; outer fragment over-riding the inner fragment. Right side, inner end 4·5 cm., outer absent.	—	—
35	,,	F. 1½	Daughter of No. 34.	Fontanelles and suture enormous; frontal bone cleft to within 1 cm. of root of nose.	Sternal ends; left 2·3 cm., right 1·5 cm. Fibrous prolongations to the coracoids.	—	Palate narrow.
36	,,	F. 1½	Daughter of No. 34.	Persistence of sutures and fontanelles; sagittal suture 2 cm. wide.	Sternal fragments, 1·5 cm. and 2·3 cm., with fibrous bands passing out to the coracoid process.	—	Pointed palate.
37	,,	F. 3½	Daughter of No. 34.	Sagittal suture and both fontanelles open.	Sternal portions 3·2 cm. on each side, with fibrous bands passing towards the coracoid processes.	—	Palate pointed and dentition irregular.
38	Schorstein.	F. 13	Father well, mother rickety; three brothers well. No syphilis or tubercle.	Large head; frontal and parietal bosses, median depression; fontanelles open at 9 years old.	Acromial two-thirds of the clavicle absent on both sides, except for a small nodule near the right acromion which was hardly visible to the X rays; sternal portions cartilaginous. Sterno-mastoid muscles attached to fragments.	Small, thin, anæmic.	Teeth bad and very irregular; slight sternal depression. Walked when 4 years old. Photographs and radiogram.
39	Pinard and Varnier.	M.	—	Head not large.	The bones in two halves on both sides.	Medium-sized, intelligent.	Palate narrow and pointed; never had syphilis. (I have been unable to consult this work, as the volume is not in any of the medical libraries in London.)
40	,,	—	Child of No. 39.	—	The bones in two halves like the father.	—	Patient dead.
41	—	—	Child of No. 39.	Natiform skull.	Both bones angled, but firm.	—	Palate highly arched.
42	—	F. 22	Daughter of No. 39.	Frontal and parietal bosses; sagittal groove; fontanelles closed.	Sternal over-riding acromial portions on both sides.	Very small, 1·51 metres.	Contracted pelvis, angling of sternum, palate narrow, dentition irregular.
43	Hamilton.	F. 38	Eight brothers and sisters normal.	Frontal bosses separated by a mesial furrow.	Sternal portions 2¼ inches long, united to the acromion process by a fibrous band better marked on the left side.	5 feet high, slight.	Scoliosis and lordosis; palate pointed, narrow; dentition very irregular and teeth badly developed. Did not walk till 3 years; double flat-foot.
44	Wolf.	M. Adult	Father had scoliosis: skull malformed like his son. Mother and 11 brothers and sisters well.	Large frontal, parietal, and occipital bosses; deeply sunk posterior fontanelle.	Sternal fragments 6 cm. Acromial parts represented by ligament better developed on the right side.	—	Scoliosis; nose deviated to the right; teeth very defective; muscles normal.
45	Hirtz and Louste.	M. 49	An only son, father dead. Only walked at 3 years old, with late dentition and peculiar aspect. Mother dead; cause unknown.	Forehead small, with prominent bosses and mesial furrow. Anterior fontanelle not closed; the posterior had closed late and irregularly. Parietals were prominent.	Sternal portions thin; left, 5 cm.; right, 4 cm.; that on right side cartilaginous.	Stood in a penguin-like attitude. Lordosis; face flat; intelligent.	Apparent exophthalmos due to depression of inferior orbital rim. Bridge of nose depressed by arrest of development of zygomatic arch. Jaw underhung; dentition late and irregular; palate pointed; palatal suture absent. Looseness of phalanges of the hands; nails affected.
46	Preleitner.	M. 12	—	Characteristics poorly shown in photograph.	Over-riding of the fragments on each side. Sternal portions 6 cm., acromial 3 cm.; adjacent ends enlarged.	Weakly aspect.	Radiogram.
47	,,	F. 8	—	Photograph shows broad bossed head.	Bone divided on both sides; sternal portions 5 cm., acromial portions 3 cm.	Photograph shows flat face.	Nose depressed; eyes deeply set. Radiograms.

No.	Name of reporter.	Sex and age.	Family history.	Head.	Clavicles.	Aspect and intelligence.	Remarks.
48	Shermann.	M. 3	Father and mother normal and well.	Frontal bosses; skull bones poorly ossified; fontanelles and frontal suture open.	Left side, rudimentary; right sternal half present alone. Scapulæ deformed; supra- and infra-spinati and posterior part of deltoid atrophied.	Normal.	Curvature of long bones needing operation. Photographs and radiogram.
49	,,	M.	—	Large square flat-topped head; marked depression behind the anterior fontanelle.	Both clavicles divided into the two halves.		—
50	,,	F. 8	Daughter of No. 49.	Fontanelles and sutures closed; marked depression at the site of the sutures.	Clavicles completely absent and X rays showed no trace; muscles normal.	Nose flattened.	Sternum depressed.
51	Gross.	F. 12	Father, mother, brothers, and sisters normal.	Enormous head, 507 mm. circumference, 174 mm. antero-posterior, and 147 mm. transverse diameters. Prominent frontal bosses; mesial furrow in frontal region, where the suture is open in its upper two-thirds.	Sternal portions 2 cm. on each side, cartilaginous. Clavicular head of pectoralis major small, of deltoid absent, of trapezius absent; sterno-mastoid normal.	Small and poorly developed; 1·18 metres high; orbits sunken.	Palate narrow; dentition irregular. Pigeon-chested, furrowed laterally; dislocation of the shoulder. Adenoids. Photograph and radiogram.
52	Spriggs.	F. 12	Father normal, mother has myxœdema; three other children well. Maternal uncle phthisical.	Cranium very bulging; frontal prominences.	Both clavicles in two halves united by ligament; adjoining ends enlarged; inner over-rides the outer part.	Face small; intelligent.	X rays show fragments very imperfectly ossified; depression of sternum. High palate; irregular dentition.
53	Poynton and Miller kindly lent the author the specimens shown.	M. ¾	Mother and father and four brothers and sisters normal.	Skull cap shown; large fontanelles and wide sagittal, metopic, and lambdoidal sutures.	Both clavicles completely absent, but well-developed bars of cartilage, partially ossified, attached to the first costo-chondral junction and base of the coracoid process by ligament. (See description in text.)		Died from marasmus. Specimens obtained post mortem.
54	Villaret and Francoz.	F. 36	Father died, 36; cause unknown. Mother died, 35; cardiac trouble and emphysema. They were first-cousins. Grandmother and five brothers and sisters normal. An uncle deaf from birth.	Fontanelles did not close till tenth year. Frontal, parietal, and occipital bosses; median frontal groove.	Left side normal, but highly arched. Right side, sternal portion 6·5 cm., overriding the acromial portion, which is small and atrophied and represents the outer third. The two united by ligament.	Slightly built, 1·43 metres.	Perforation of the palate posteriorly, the palate being very arched. Dentition poor and irregular; supplementary canine; jaw underhung. Nose deviated to the left. Orbital margins below are not prominent, giving the appearance of exophthalmos. The transverse process of the seventh cervical vertebra more prominent on the affected side; slight scoliosis; narrow pelvis.
55	,,	F. 9	Daughter of No. 54, born at 7 months. Father was alcoholic and epileptic. This is the third child. (First, born at 7 months, died in 5 hours; the second, full time, died at 21 months from tubercle. The first two children were by a different father.)	Frontal, parietal, and occipital bosses; median frontal furrow. Ossification completed in seventh to eighth year.	The clavicles on both sides are in two halves and are similarly arranged. The sternal fragments are 4 cm. long and are cone-shaped. The acromial fragment is small, moves with the scapula, but is little moveable on it. The two portions are united by a fibrous cord 2 cm. long. The coracoid processes are easily felt. X rays showed the fragments to be cartilaginous. Muscles normal.	Height, 1·14 metres.	Palate not perforated, though arched, with depression at its highest point; teeth small and irregular; lower lips rather large.
56	,,	M. 6	Fourth child of No. 54 born at full time.	Frontal, parietal, and occipital bosses; mesial frontal furrow deep. Anterior fontanelle not closed.	Both bones in two parts; sternal fragment left side 4 cm., right side 3 cm. The acromial fragments slightly more marked than in the last case. No fibrous attachment to be felt.	Nose depressed, orbits deep; face is overhung by the prominent forehead.	The head of the humerus is easily dislocated on both sides owing to the laxity of the ligaments. The transverse processes of the seventh cervical vertebra feel prominent. Palate arched; dentition irregular.
57	,,	F. 7/12	Fifth child of No. 54.	The same as the last case; large open fontanelles.	Clavicles normal.	—	—
58	Couvelaire.	F. 23	Mother dead; cause unknown. Father living and well.	Large frontal bosses, mesial frontal furrow; anterior fontanelle open.	Clavicles only represented by nodules 2 cm. long articulating with sternum and to which are attached the sterno-mastoid muscles. No fibrous prolongation felt.	—	Dentition bad. Lordosis of spine; genu valgum more marked on left side.
59	,,	M. 10/12	Second child of No. 58. First child normal.	Sutures and fontanelles large and open.	Clavicles absent on both sides.	—	—

36, and 48), when the sternal end alone is present, the condition is bilateral; of these exceptions, the clavicle on the opposite side is normal in one, in two portions in three, and rudimentary in the fifth. In marked contrast to this is the number of cases in which the acromial end alone is present, only two exemplifying this arrangement. In Case 6 a small nodule passing from the acromion to the coracoid process is all that represents the clavicle on the right side, the left bone being normal; in Case 26 the abnormality is bilateral. In neither case is any ligament mentioned passing towards the sternum. It can therefore be laid down as a rule to which there are very few exceptions: firstly, that when half the clavicle is absent it is the acromial portion which is wanting; and secondly, when this condition is present it affects both sides.

When both halves of the bone were present but were ununited (31 instances—14 on the left and 17 on the right side) the condition was usually bilateral. In three instances, however, the opposite bone was normal (Cases 5, 12, and 60); in two it was excessively arched (Cases 11 and 54); and in one it was distinctly notched (Case 14). Great variation in size is exhibited by the two fragments, but the inner is almost invariably the larger of the two, as is well seen in the first case which came under my own observation. In this case, too, the ligament binding together the two portions illustrates the bond of union usually found when both fragments are well developed. In only one or two cases when both fragments are well represented is the absence of fibrous or ligamentous tissue noted.

Where the sternal end alone is present it is interesting to examine the records, for in 26 instances (14 on the left and 12 on the right side) a fibrous or ligamentous prolongation is found extending outwards. When these prolongations are tabulated according to their position, it is singular to find that the majority pass, not to the acromion, but to the coracoid process. Scheuthauer found on dissection a band passing to the upper part of the glenoid cavity having in its outer end a process of bone an inch in length. This state of affairs was the same on both sides.

Table of Ligamentous Prolongations.

	Left.	Right.		Left.	Right.
To coracoid ...	10	9	To rib	0	1
To glenoid ...	1	1	To acromion ...	1	1

Seymour Taylor and Walsham each remarked that this ligament appeared to represent the costo-coracoid membrane. Martin, in the earliest record we have, gives a clear account of a nodule of bone plainly felt connecting the sternal end of the clavicle to the coracoid process; the side, however, is not mentioned.

The primitive shoulder girdle is composed of one dorsal and two ventral bars; the anterior ventral bar is the precoracoid, and the posterior is the coracoid. In fishes a dermal plate is added to the precoracoid, and the fusion of these elements is said to give rise to the clavicle in higher vertebrates. In birds, as flying necessitates a pectoral girdle firmly adjusted to the trunk, the coracoid and clavicle are well developed. In all mammals, except monotremes, the coracoid as a bone reaching the sternum practically ceases to exist. In carnivora and herbivora the clavicle also is undeveloped, but in man and other animals which use their upper extremities in climbing, eating, and similar actions besides mere progression, the clavicle is well represented, although only uncertain traces of the coracoid and precoracoid remain.

Ossification is stated to commence in the clavicle in the middle of the shaft, and to extend through the underlying cartilage to its extremities. The process begins in this bone earlier than in any other. An ossific centre can be recognised in it about the sixth week, but Couvelaire has detected it even as early as the thirtieth day. The inner end has a secondary epiphysis which appears later.

Considering the affection hereditary cranio-cleido-dysostosis, we find that it affects those bones which develop in membrane, preventing and retarding their development and ossification; therefore the portion of the clavicle which is most affected will be that part which develops primarily in membrane. Among the cases we find that the sternal portion is present alone on the left side on 23 occasions and the acromial portion alone only once; while on the right side the figures are 27 and 2 respectively. That is to say, the sternal portion was present alone on 50, and the acromial portion alone on only 2 occasions. From this we are driven to the conclusion that the outer end of the bone is the part which arises from membrane, while the inner originates in cartilage. Whether this membranous portion represents the dermal structure found in fishes, or is a membranous structure which has arisen *de novo*, as Mr. Jenkins has suggested to me, I am unable to say, but that it is membranous in origin is, I think, beyond doubt. The frequency with which the bone is met with in two separate fragments (31 times), or in which the bone, although joined, shows evidence of its two halves by angling or notching (7 times), is strongly in favour of a double origin. Additional evidence of the dual origin of the bone may reasonably be adduced, however, from other well-recognised characteristics.

1. The supra-clavicular nerve is occasionally included in a foramen on the anterior and upper aspects of the bone at a point a little external to the centre. This inclusion indicates that the nerve has been surrounded by the fibres of the growing bone, possibly, though not necessarily, at the site of junction of the two portions.

2. On rare occasions a vein, passing from the cephalic to the external jugular, is included in a foramen at the same situation. This vein represents the original termination of the cephalic vein still to be seen in some animals, but which has been diverted in man, presumably by the development of the clavicle. Its inclusion may be accounted for in the same manner as the nerve.

3. The curvatures of the bone differ, the inner being in the opposite direction to the outer. These are well seen in early life before muscular action has come into play; indeed, they are well seen in cases where the bone is present in two halves, and muscular action can have had no effect.

4. There is very frequently a tubercle at the junction of the middle and outer thirds of the bone on its anterior aspect, which goes under the name of the deltoid tubercle on account of its supposed association with the development of that muscle. This tubercle can often be felt well marked in children of poor musculature at an age when muscles have as yet left little impression of their bony attachments. It is also significant that on the under and posterior aspects of this part of the bone there is another prominence developed—namely, the conoid tubercle. These tubercles may be analogous to the prominent line frequently left at the junction of epiphysis with diaphysis.

5. On looking at the configuration of the bone it is at once seen that the inner two-thirds are cylindrical, like most limb bones developed from cartilage, while the outer third is flat and tabular, resembling more the membranous cranial bones.

6. In about 45 per cent. of bones a small nutrient foramen can be seen on the under surface between the deltoid and conoid tubercles, some distance to the outer side of the main nutrient foramen.

Many observers have endeavoured to recognise the morphological portions of the clavicle by means of microscopic sections and different staining reactions, but so far without throwing any very clear light upon the subject. Gegenbauer, whose description has been followed in most anatomy books, placed the primitive membranous portion in the middle of the bone, and stated that cartilage developed later at each end, and from these cartilages the bone increased in length. Kölliker, from the investigation of embryo rabbits of 2 millimetres, thought the bone began to ossify in the centre over a bar of cartilage, this cartilage differing in some respects from that found elsewhere in the body. Couvelaire, on cutting sections through human embryos of 19 and 50 millimetres long, came to the conclusion that the bone ossified from a core which was completely surrounded by cartilage. Paterson, from the microscopic examination of sections of rabbits, rats, and human embryos, formed the opinion that "the clavicle possibly contains more than one morphological unit (judged by its ossification directly in the outer part and indirectly through cartilage in its inner part)." My own investigations strongly support this view. My former colleague, Mr. Jenkins, by means of serial sections, has constructed a wax model of the shoulder girdle in relation to the trunk of a human fœtus of 16 millimetres long. The model shows the clavicle in two parts, both apparently cartilaginous. Mr. Jenkins believes that the inner mass forms the sternal end of the clavicle, while the outer mass disappears, the acromial end being developed from separate mesodermal tissue.

If, then, we admit that the bone is made up of two halves

and the outer represents the membranous portion, what does the inner represent? And here, although absolute proof is impossible, the different possibilities are worthy of consideration. These possibilities are two in number.

1. That the inner end is a new formation altogether, and does not represent anything found in the primitive shoulder girdle of lower animals.

2. That the inner end represents part of a primitive bar of cartilage or bone extending from the glenoid cavity to the sternum, of which the other parts are represented by the coraco-clavicular ligaments and part of the coracoid process.

The first of these alternatives has nothing to recommend it, while very serious objections can be raised against it. For in all developmental errors those structures which have the oldest phylogeny appear earliest and therefore suffer least, while the more recent the modification the later it appears, and consequently the more will it be affected. Now, according to the table of defects in the clavicle which has been drawn up we see that the outer end suffers far more frequently than the inner, which therefore must be looked upon as the more ancient structure.

We are in consequence thrown back on the second of the two alternatives, and everything points to the probability of this being the more correct of the two views. In many of the cases in which the acromial end of the clavicle is suppressed, this bar, extending from the sternum to the glenoid cavity, is well represented by the more or less developed inner end of the clavicle, by the ligament already mentioned proceeding outwards to the coracoid process, and by the base of the coracoid itself. When both halves of the bone are present but ununited this bar is represented by the inner half of the bone, the ligament joining the two halves, the coraco-clavicular ligaments and the coracoid as before.

While, therefore, there can be little doubt that the inner portion of the clavicle does represent a part of this primitive bar, there still remains the task of deciding whether this bar is a precoracoid or a coracoid, and here again, though it is impossible to dogmatise, the possibilities may be set the one against the other. In endeavouring to trace, in the component parts of the greatly modified and highly specialised shoulder girdle of man, the representatives of the elements of the primitive pectoral girdle, I can only discuss those views which this investigation indicates as the more probable. The chief possibilities may be stated as follows:—

1. The coracoid is represented by the base of the coracoid process, the coraco-clavicular ligament, and the inner two-thirds of the clavicle, the precoracoid being represented by the tip of the coracoid process and the costo-coracoid ligament.

2. The coracoid is represented by the base of the coracoid process only, and the precoracoid by the inner two-thirds of the clavicle and the costo-clavicular ligaments.

3. The coracoid is represented by the tip of the coracoid process and the costo-coracoid membrane, the precoracoid being either absent or, as in the second possibility, represented by the inner two-thirds of the clavicle and the costo-clavicular ligaments.

The coracoid process develops from a primary ossific centre which appears during the first year at the base and extends, not only towards the apex, but also towards the base, and forms part of the glenoid cavity. Several secondary centres, which appear later, only form a small portion of the process. Sabatier holds that the basal portion alone represents the ancestral coracoid, and as far as the coracoid process is concerned this view seems to be supported by two significant facts.

First, it is in the basal portion of the bone that the primary centre of ossification appears, pointing strongly to the fact that this portion of the bone has the oldest phylogeny. Secondary ossific centres, we know, have frequently but a short ancestry, being developed in response to the requirements of function. A good instance of this is seen in man, where the adoption of the erect attitude has rendered the older or reflected attachment of the rectus femoris muscle almost useless, and in consequence a new or straight tendon of origin has appeared; in connexion with this there has developed a small secondary epiphysis capping the anterior inferior spine of the ilium, which is present in no other animal. The same reason—namely, requirements of function—probably account for the appearance of the variable number of small secondary epiphyses in the coracoid process. The short head of the biceps and the coraco-brachialis probably account for the appearance of one or more at the apex of the process; while the long head of the biceps may account in the same manner for the small scale-like epiphysis which is sometimes present at the base.

A second point in favour of Sabatier's view is that this primary basal epiphysis extends downwards to take part in the formation of the glenoid cavity, for throughout the range of animal life the coracoid is a far more important factor in the shoulder girdle than is the precoracoid, and is the element which takes part, and sometimes takes the largest share, in the formation of the glenoid cavity, the remainder of the joint cavity being formed by the scapula, while the precoracoid is altogether excluded. As the ligament in the specimen from my second case is attached to the back of the coracoid near its base, it is fair to assume that it is probably in morphological unity with this portion of bone and is probably part of the old coracoid. This means that the specimen represents an almost complete coracoid bone, made up of the inner two-thirds of the clavicle, the base of the coracoid process, and the intervening coraco-clavicular ligament, and therefore answers to the conditions laid down for the coracoid in possibility No. 1. The relationship of parts revealed in the wax model, already referred to, also seems to support this view.

There still remains to be accounted for the tip of the coracoid process and the costo-coracoid ligament. This ligament, sometimes termed the bicornuate ligament, is a distinct thickening of the costo-coracoid membrane, running from the tip of the coracoid process along the lower margin of the subclavius muscle to the cartilage of the first rib, and can frequently be traced on the sternum close to the sterno-clavicular articulation. It is sometimes well marked in man, and occasionally presents in its substance chondral particles (Sutton), but is better marked in the quadrumana. This ligament and tip of the coracoid process would necessarily represent, in a rudimentary condition, the precoracoid bone as laid down in possibility No. 1, and not, as some believe, the coracoid bone itself. For if we allow for the moment the costo-coracoid ligament and tip of the coracoid process to be the representatives of the coracoid bone, as in possibility No. 3, it would follow that the base of the process, which from its manner of ossification is evidently not in series with the tip, must consequently be the precoracoid; and we here have the precoracoid forming part of the glenoid cavity to the exclusion of the coracoid—a state of affairs which, I believe, is unprecedented throughout the animal kingdom, and certainly unknown in the primitive type. Possibility No. 3, therefore, does not commend itself.

Returning to possibility No. 1 it will be argued that the reversed relationships of the two bars, the coracoid being cephalad to the precoracoid, renders this view untenable. But the reversed relationship is more apparent than real, for the inner ends of the two bars are in close proximity at the sternum, while of the outer ends, the coracoid is the base of the coracoid process, and the precoracoid is the tip of the same process of bone. In the former the line of the bar is angled in a cephalad direction at the coraco-clavicular ligaments, while in the latter the tip of the coracoid process is curved forwards and downwards in a caudad direction owing to the function it has assumed—namely, that of giving origin to the short head of the biceps, which according to Brodie was originally attached to the acromion process, the outer part of the coraco-acromial ligament representing the old tendon of origin. It is only fair to assume that the present shape of the coracoid process is largely influenced by its present function, and that originally the tip was nearer the head than the base of the bone, and therefore, the true position of the tip of the process and the costo-coracoid ligament is, as the name indicates, precoracoid.

Sutton's view, that the precoracoid bar is represented in man by the interarticular cartilage at each end of the clavicle, is not borne out by the condition found in the shoulder girdle of any of this series of cases, and fails to take into account the different origins of the two portions of the clavicle. Speaking of the interarticular fibro-cartilage at the sternal end Professor Paterson states that "the meniscus is not to be regarded as homologous with the rodent supra-sternal cartilage, but is rather to be associated morphologically with the cartilaginous inner end of the clavicle." If, then, as

we have assumed, the inner end of the clavicle is the inner end of the old coracoid process, this meniscus at its inner end may quite well represent the epicoracoid bone found in monotremes. Howe's view that the epicoracoid is represented by the tip of the present coracoid process leaves the costo-coracoid ligament unaccounted for. Against the second possibility may be urged the grave objection that it leaves the tip of the coracoid process and the costo-coracoid ligament unaccounted for. Considering, therefore, the relative merits of these different views it must be admitted that the possibility which is placed first appears to have most in its favour, while the reasons which can be urged against it are much less weighty than those against either of the other two.

Theories as to Cause.

A great many opinions as to the cause of the condition hereditary cranio-cleido-dysostosis have been advanced. Alcoholism, tuberculosis, syphilis, and rickets have all been advocated; but the accuracy of these opinions appears less and less probable with the growth of our knowledge of the subject. The position that hereditary cranio-cleido-dysostosis bears to achondroplasia is helpful in enabling us to obtain an idea of the true nature of both these affections, the former being a condition of maldevelopment of the membrane bones, while the latter is a condition affecting the development of those bones which originate in cartilage.

It might be suggested that the cause in both affections is due to the presence or absence of certain chemical constituents which are necessary for the correct ossification of membrane bones in the one case and of cartilage bones in the other: in much the same way as we know that hæmophilia must be due to a hereditary absence from, or presence in, the body of certain chemical constituents. Couvelaire advanced a somewhat similar view when he said that hereditary cranio-cleido-dysostosis was "the expression of a general taint with a predominance in certain osseous groups." This idea was prompted by the recognition of the frequency with which other malformations were met in individuals suffering from this condition.

In support of this the following defects are noted in this series of 60 cases: peculiarities in the shape of the sternum, 10 cases; scoliosis, lordosis, or kyphosis, 11; prominence of the transverse processes of cervical vertebra, 6; genu valgum, 4; peculiarities of the hands, 4; curvatures of the long bones, 3; and flat and pigeon chests, 2 each. Besides these anatomical departures from the normal, a large number of the patients are mentioned as undersized and of poor general development. In some the intelligence seemed to be diminished, but this was by no means the case in the majority. Couvelaire gives no hint as to what he thinks this taint may be. We are, therefore, constrained to leave the discovery of the cause until such time as we shall have a more accurate knowledge of the forces, chemical or vital, which govern development.

Brook-street, W.

TWENTY CASES OF PULMONARY TUBERCULOSIS TREATED BY CONTINUOUS ANTISEPTIC INHALATION.

BY DAVID B. LEES, M.D. CANTAB., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

TWELVE months ago, on Nov. 2nd, 1909, I read before the Therapeutical Section of the Royal Society of Medicine a paper on the Physical Signs of Incipient Pulmonary Tuberculosis and its Treatment by Continuous Antiseptic Inhalations.[1] In this paper I gave full details of the method of treatment advocated, and narrated 30 cases of incipient or early pulmonary tuberculosis in which it had been employed with success. Now that another year has elapsed I desire to record the present condition of these cases, and to add an account of 20 subsequent cases in which the same method of treatment has been used.

My summary of the results a year ago was as follows:—

> I consider 22 out of the 30 as certainly cured. In 13 of them the cure has stood the test of time, for they have all remained well and in active work for a whole year. These are Cases 2, 3, 4, 5, 6, 7, 8, 9, 12, 13, 14, 15, and 16. To these may probably be added Case 1. Eight other cases—Nos. 18, 19, 21, 22, 24, 25, 26, and 29—are apparently quite well, but they have not yet stood the test of time. Five cases—Nos. 10, 11, 17, 20, and 27—I look upon as nearly cured. Only three cases remain about which one feels any doubt as to the favourable issue; they are Nos. 23, 28, and 30, and all these three cases have improved very considerably.

In a subsequent letter[2] I stated that "in all these three cases the doubt has been replaced by a practical certainty of cure."

At the end of a year after the reading of my paper I have to report that of the 14 cases in the first group at least 12 are still quite well and in constant active work—these are Cases 2, 3, 4, 5, 6, 7, 9, 12, 13, 14, 15, and 16. About the two others (Nos. 1 and 8) I have no further information. Seven of the eight cases whom I classed as "apparently quite well" have remained quite well during the last year and in active work. These are Nos. 18, 19, 21, 24, 25, 26, and 29. The eighth (No. 22) had a slight relapse in December and January at a time when he had reduced the use of the inhaler to two hours daily and was working hard for ten hours a day. He lost 4½ pounds in weight, the dull areas in his lungs became larger, and the air-entry feeble, with slight crepitus at his apices. But a fortnight in bed with persistent inhalation restored him. On March 8th, 1910, he had gained 9 pounds in weight and his physical signs were much improved On Oct. 26th, 1910, he writes that he has been continually hard at work since February, and that he is able to do his business without undue fatigue. He has still a slight cough.

Of the five cases—Nos. 10, 11, 17, 20, and 27—which I described as nearly cured, Case 10 wrote to me some months ago that she was quite well and could perform her duties without fatigue; about Nos. 11 and 17 I have no further information. No. 20 had a slight relapse in January, 1910, after having discontinued the inhaler for several weeks. A return to the treatment quickly produced an improvement, and she again gained weight, but signs of a small cavity in the outer and upper part of the right lung became evident. Under persistent treatment these signs progressively diminished, and in October, 1910, she is stated to be apparently quite well. Case 27 is unusually chronic, and has had pain in her right chest from time to time, but the physical signs are slowly but steadily improving. She has no cough and is increasing in weight.

Finally, as to the three cases Nos. 23, 28, and 30. No. 30 writes on July 9th, 1910: "It is exactly a year to-day

[1] The paper was published in the British Medical Journal of Dec. 11th, 1909, and also in the Proceedings of the Royal Society of Medicine.

[2] Brit. Med. Jour., Dec. 25th, 1909.

that I was taken ill. My weight is 11 st. 7 lb." [total gain 13½ pounds]. "My breathing is very good, and I have a good appetite. I am enjoying very good health." He has been actively at work. The little boy, No. 28, has remained quite well, and his physical signs are quite satisfactory. He has gained 7 pounds in weight. Case 23, the most severe of all the thirty except Case 3, writes on Oct. 25th, 1910: "I feel quite well. I have been back at business since April, and am stronger than when I returned. I feel no fatigue after the day's work, and have played cricket and golf all the summer. When I returned in April my weight was 12 st.; it is now 12 st. 4 lb."

CASE 31.—The patient, aged 69 years, was seen at his home in consultation with Dr. Hickley of South Lambeth-road on July 20th, 1908. Not a temperate subject. Had an operation for hæmorrhoids six months ago. Hæmoptysis for a week three months ago. Thinner lately, but had very little cough. Four days ago dyspnœa developed suddenly, and was found by Dr. Hickley to be due to pneumothorax on the left side. Gradual improvement took place, but when I saw him the left side was still to some extent distended and the heart displaced to the right. Dullness at all four apices, especially the two lower apices, with crepitation, blowing expiration, bronchophony, and audible whisper. Considering the age of the patient, the history of chronic alcoholism, the pneumothorax, and the marked evidence of pulmonary tuberculosis, the prognosis appeared to be almost hopeless. But he was advised to adopt the plan of treatment by continuous antiseptic inhalation (of which full details were published in my paper referred to above), in the hope of securing at all events some alleviation and improvement. Accordingly he practised continuous inhalation by means of a Yeo's inhaler for six weeks, during the first three of which he remained in bed. He then gave up the inhaler and went to the seaside for a fortnight. He then returned to business, and more than a year later (January, 1910) Dr. Hickley found that he was well and at work. In October, 1910, Dr. Hickley reported that he is still well, and leaves home for his business in the City every morning before half-past eight.

CASE 32.—The patient, aged 38 years, came for advice on June 28th, 1909, on account of attacks of epigastric discomfort with flatulence and shivering, which had recurred about twice a week since he paid a visit to New York three years before. No vomiting, hæmatemesis, or melæna. Smoked "a good deal." Moderate dilatation of the stomach was found on examination, and in addition it was noticed that small dull areas were present at both apices of the left lung only. He had a short rather frequent cough. On August 10th he was no better, and had lost 2 pounds in weight; the dull areas at the apices of the left lung were larger and a little crepitus was detected, but the right lung was still normal. On Sept. 27th the condition was unaltered, and lavage of the stomach was advised. This was performed by Dr. Bindloss of Harrow, and gave much relief. On Nov. 3rd the stomach was found less distended, but the shivering attacks continued, and the possibility of malaria was considered. The spleen was normal. He had lost 3 pounds in weight. There was no cough or sputum, but fresh signs of tubercle were found in the right lung, as well as in the left, with tenderness and crepitus. A blood examination by Dr. Spilsbury showed "red corpuscles, 5,400 000; hæmoglobin, 110 per cent.; white corpuscles, 3900 (polymorphonuclears, 48 per cent.; small mononuclears [lymphocytes], 48 per cent.; large mononuclears, 4 per cent.)" and the conclusion was drawn that the absence of anæmia was against the idea of malaria, while the increased proportion of lymphocytes was in favour of tuberculosis. A little sputum was obtained, and found to contain epithelial cells and some pneumococci, but no tubercle-bacilli. The opsonic index to tubercle was found by Dr. Parry Morgan to be 1·15. On Nov. 11th I saw the patient at his own home in consultation with Dr. Bindloss, when we again found the dull areas in both lungs. He was kept in bed and used continuous antiseptic inhalation (as above defined), the inhaler being removed only at meal-times. Four grains of quinine were administered three times a day. On Nov. 18th no more shivering had occurred, and the dull areas were all distinctly smaller. On the 30th, the treatment having been continued, he was found to have gained 6 pounds in weight, the dull areas were still diminishing, and no more shivering had occurred. There was still a little fine crepitus at the apices. He continued the persistent inhalation for three weeks longer, and on Dec. 20th had gained 1½ pounds more. Omission of the quinine was followed by a slight relapse of shivering and gastric symptoms, but in February, 1910, he wrote: "I am feeling better and weigh 10 st. 1½ lb."—a further gain of 1½ pounds, or 9 pounds in all. In October, 1910, he wrote that he had done his full work since January, that his digestion was now "almost perfect," that the shivering attacks had gradually become less frequent and had been absent for the last five weeks, and that he coughed only when he "caught cold." His weight was now 9 st. 11½ lb. in summer attire.

CASE 33.—A patient, aged 39 years, of Dr. R. H. Wilkin, Wickham-brook, Newmarket, seen on Oct. 13th, 1909. He had had cough two years; hæmoptysis 14 months ago; has not worked since; dyspnœa 12 months; night-sweats; and weight fell from 11 st. 11 lb. to 10 st. 9 lb. Then he improved, lost his night-sweats, and gained weight; but a fresh hæmorrhage occurred three months ago. His weight now was 10 st. 13 lb.; there were dull areas at all four apices, especially at those on the right side; feeble air-entry, with a little crepitus, but no bronchial breathing or audible whisper. Clearly he had offered considerable resistance to the disease; hence further improvement might be hoped for in spite of the long duration. He was treated by continuous antiseptic inhalation. I did not see him again until June 15th, 1910, when he reported that he had worn the inhaler about 20 hours daily for five months, and 18 hours daily for the last three months. He had improved at once and steadily until a month ago, when sudden cold east winds increased his cough. He felt much better, slept well (before using the inhaler he was often kept awake by cough until 2 A.M.), enjoyed his food, and had no indigestion. He looked well, and coughed once only during the examination, but he had lost 3 pounds in weight. His dull areas were distinctly smaller, and hardly any crepitus could be detected. In October, 1910, Dr. Wilkin wrote that the patient was "just holding his own," and that he had not again lost weight, but that he still coughed a good deal and expectorated occasionally. He was not yet able to do even half a day's work.

CASE 34.—A patient, aged 30 years, of Dr. J. W. Ellis of Swavesey, Cambridge, seen on Oct. 18th, 1909. He had been ill eight months, recurrent slight hæmoptysis; "brings up thick phlegm." Teeth very decayed and foul. Large areas of dullness at all four apices and several lower areas. Tenderness, very feeble air-entry, marked crepitus, and some bronchial breathing and audible whisper. The disease was extensive and advanced; the prognosis appeared to be grave. He was very feeble and looked very ill. Under continuous antiseptic inhalation, carried out under special difficulties and rather imperfectly, he improved steadily. On Nov. 13th, 1909, he had gained 5 pounds in weight in three weeks, the dull areas were smaller, and less crepitus was present, with hardly any bronchial breathing or audible whisper. On Dec. 18th he had gained 2 pounds more (7 pounds in all), and the physical signs were still improving. On Feb. 24th, 1910, he was going on well, and had almost lost his cough, his appetite had improved, and he had been able to do two or three hours' work every day. No crepitus could now be detected in his lungs. In October, 1910, he wrote: "I am able to do my work from about 6 o'clock in the morning until about 5.30 at night," but that he weighs 7 pounds less than in February. He had not used his inhaler much of late, and had given up the malted milk. His cough was variable, but at present better.

CASE 35.—The patient, aged 31 years, unmarried, was brought by Dr. J. Ashton of St. John's-hill, Battersea, on Nov. 16th, 1909. She had had cough for six months at least, slight hæmoptysis four months ago. Appetite poor. Dullness at all four apices, and four lower areas, with crepitus, but no bronchial breathing or audible whisper. After treatment by continuous antiseptic inhalation for a fortnight she stated that the cough was "ever so much better," and she had gained 2½ pounds in weight. The physical signs had already begun to improve. Unfortunately, in December she had an attack of colitis, which reduced her strength, and the inhalation was less regularly employed. In February her cough became worse, and it was found that all her dull areas were larger. She was therefore kept in bed for a fortnight, and the inhaler was used persistently except at meal-times. This soon checked the cough, which had become severe, and she looked brighter, but she had lost a pound in weight, and the dull areas were still slowly increasing. The situation of her home in London was such that it was difficult to obtain sufficient fresh air, so she was sent to Ventnor, where the windows were kept widely open and she used the inhaler continuously. After five weeks she returned much improved, and the inhalation treatment was again reduced. Her condition once more became less satisfactory. But a return to more thorough treatment again produced an improvement, and when I saw her on Oct. 2nd, 1910, she had gained 3½ pounds in the last seven weeks, and the physical signs were much more satisfactory. Total gain, 7½ pounds. She is to spend the winter at Arosa in Switzerland under medical observation, and is to practise antiseptic inhalation eight hours a day for the first two months and six hours a day subsequently.

CASE 36.—The patient, aged 53 years, married, was sent by Dr. G. A. Simmons of Westminster on Nov. 19th, 1909. She had had short hacking cough on and off for four years, with occasional streaks of blood and small clots in the expectoration. Her mother had died from phthisis at 52, and an uncle and two aunts had died from the same disease, in two cases after only a few weeks' illness. Dullness was present at all four apices and several lower areas, with extensive crepitus and apical tenderness. She was advised to remain in bed for ten days and practise continuous antiseptic inhalation. This was carried out, but the calls on her time were such that subsequently she could not use the inhaler more than two hours daily. She visited me again three months later (Feb. 15th, 1910), when I found that she had gained 9 pounds in weight, that the dull areas were all smaller, that the tenderness had entirely disappeared, and that no crepitus could be heard. I have not seen her again since February, 1910, but in answer to my inquiry Dr. Simmons writes (Oct. 13th, 1910): "Mrs. —— recovered completely, as far as could be made out, from her lung trouble; but she died about three months ago from cerebral hæmorrhage."

CASE 37.—The patient, aged 28 years, married, was seen at her home in consultation with Dr. Ashton of Battersea on Dec. 14th, 1909. Cough, called "nervous," for four years. No hæmoptysis. The cough became bad and accompanied by expectoration seven months ago. *She had been treated for six months by tuberculin injections given regularly every week.* When Dr. Ashton was called to see her in November, 1909, she was exceedingly ill, seemed collapsed, and had a temperature of 103° F. He at once stopped the inoculations, and suggested that she should adopt the treatment by continuous antiseptic inhalation as advised for Case 35. This was begun on Nov. 17th, 1909. Improvement followed immediately. After a fortnight the temperature had fallen to 101°, after a second fortnight it was normal. Her condition improved rapidly and steadily. When I saw her with Dr. Ashton on Dec. 14th, 1909, she was sitting up in bed, happy and smiling. Her husband and her mother bore testimony to the extraordinary improvement in her condition. I found extensive signs of tuberculous pulmonary disease and evidence of a pleural effusion on the left side. This was aspirated by Dr. Ashton and a pint of clear serous fluid was withdrawn. After this there was further improvement and she was able after a while to go out of doors.

More than four months later, in May, 1910, Dr. Ashton sent her to my house for an opinion about a small swelling at the site of the aspiration, from which pus exuded. I found that there was still much dullness and absence of breathing at the left axillary base in the neighbourhood of this opening, that the left side was very little used in respiration, and that there were signs of a dry cavity at the right apex. She was admitted into St. Mary's Hospital through the kindness of my colleague Dr. Willcox, and small pieces of the eighth and of the ninth ribs were removed by Mr. Clayton-Greene, and a drainage-tube inserted. Her general condition improved after this operation, and she returned home, but the discharge continued and she gradually grew weaker. Four months later she was readmitted into St. Mary's Hospital in a moribund condition. A necropsy was made by Dr. Spilsbury on Nov. 9th, 1910. The left lung was quite collapsed. Its upper lobe was wholly converted into a branching cavity. A smaller cavity existed below the apex of the left lower lobe, which had ruptured into the left pleura; the rest of this lobe was collapsed. The right upper lobe was universally adherent to the pleura and contained a large cavity. A smaller cavity existed below the apex of the right lower lobe. Much old fibro-caseous tubercle in base of upper lobe and in the middle lobe. Only the lower half of the right lung could have been capable of respiratory function. No caries of rib.

CASE 38.—The patient, aged 23 years, unmarried, was sent to me on Dec. 18th, 1909, by Dr. C. J. Horner of Walthamstow, who had read my

paper already referred to. She had had cough about a month, occasional night-sweats, loss of weight, some pyrexia (to 100° F.), and occasional pain at the left posterior base. Slight dyspepsia. No hæmoptysis. Her weight now was 8 st. 1½ lb.; two years ago it was 8 st. 10 lb. Dullness at all four apices, and two lower areas in the right lung, with poor air-entry but no crepitus, no prolonged expiration, and no audible whisper. Marked dullness and distinct pleural friction-crepitus at the left posterior axillary base. Under treatment by continuous antiseptic inhalation her cough ceased within a week, and there were no more night-sweats. The inhaler was worn persistently. On Jan. 18th, 1910, she had gained 3½ pounds in weight; there was better air-entry and very slight crepitus at the end of inspiration; the friction at the left base had now disappeared, and the area of dullness at this place had resolved itself into two separate dull areas. She felt so much better that she desired to go back to her work as a teacher. On Jan. 30th, 1910, she looked well and had a good colour. She felt quite well, the dyspepsia had disappeared, and no cough since the last visit. She had gained 3 pounds more in weight. The dull areas were all much smaller; a little occasional crepitus could still be heard. She was permitted to return to work. On Feb. 25th, 1910, she had gained 2 pounds more, making a total gain of 8½ pounds, and had now her normal weight of 8 st. 10 lb. She had done her full work as a school-teacher for a month without fatigue. She was advised to use the inhaler six hours a day for three months longer and to practise breathing exercises.

CASE 39.—The patient, aged 29 years, was sent by Dr. Hingston of Liskeard on Jan. 29th, 1910. He had had cough for some months; no hæmoptysis. His father died from phthisis at 64; a brother died from the same disease at 35. Dullness at all four apices and four lower areas; poor air-entry and slight crepitus, but no prolonged expiration or audible whisper. Weight now 12 st. 4½ lb.; he formerly weighed 13 st. Under continuous antiseptic inhalation he improved at once. On Feb. 22nd, 1910, he felt "much fitter, in fact quite well," had lost his cough, and had gained 6½ pounds in weight. His dull areas were all smaller, there was now good air-entry at the left apex, rather poor entry at the right apex, with slight prolongation of expiration at the right apex posteriorly, and slight tenderness and some inspiratory crepitus at the right lower apex; no other morbid sounds. On March 22nd, 1910, he felt "extraordinarily well" and "better than he had felt for two years." Had inhaled for eight hours daily and at night. The physical signs showed further improvement. In April and May he travelled to Egypt and the Mediterranean, still using his inhaler on an average four hours daily. He ascended the Great Pyramid so fast that he tired out his Arabs, and felt "perfectly fit" after an hour's "very hard climb" on Vesuvius. As the result of this hard exercise his weight had fallen to 12 st. 2 lb., but he felt and looked very well. On July 23rd, 1910, he stated that he was quite well and had walked 28 miles without fatigue.

CASE 40.—The patient was a clergyman, aged 47 years, sent by Dr. T. G. Lithgow of South Farnborough, on Jan. 30th, 1910. "Caught cold" in October, 1909 (had been regularly visiting one of his parishioners suffering from phthisis who died in March, 1910); felt very ill during the week following Christmas. "Very violent cough with heavy yellow expectoration, and a few streaks of blood" during the last three weeks. Dull pain over his chest lately, and several attacks of severe dyspnœa had occurred, lasting from 10 to 15 minutes. His appetite was poor, he slept badly, and felt quite unfit for work. I found large dull areas at all four apices, and four lower areas, with poor air-entry but only slight crepitus, indicating an extensive pulmonary tuberculous infection but in an early stage. There was obvious dyspnœa during the examination, with deep breaths and frequent short cough. His nervous tone was very low, he started when gently percussed, and his knee-jerks were much exaggerated. Some years previously he had experienced a "nervous breakdown," and of late excess of study and hard work, with other unfavourable circumstances, had much reduced his strength.

The prognosis appeared to be extremely gloomy. He was advised to go to bed at once on his return home, to practise continuous antiseptic inhalation, and to take milk and malted milk at frequent intervals. On the sixteenth day of his use of the inhaler his wife made the following note: "Temperature nearer normal; sleep natural (seven hours); cough much less; pain in lung gone; catarrhal condition almost gone; emaciation (of face) less; breathlessness better; hearing better; nervous irritation gone; mental depression better." On Feb. 23rd, 1910, Dr. Lithgow reported: "He came downstairs yesterday and feels better. No cough while wearing inhaler, but fresh air seems to irritate. Temperature has on five occasions since 30th Jan. been barely 99° F.; never above. Dyspnœa less." I found that he had gained 4½ pounds in weight; that his nervous tone was better; that nearly all the dull areas were smaller; that there was more entry of air and very little crepitus. He was advised to apply for six months' leave of absence, but to remain at home for the present, using the inhaler persistently in his own house and garden.

On March 16th, 1910, he had gained an additional five pounds (or 9½ pounds in all); his physical signs were still improving, and no sign of breaking down of lung had appeared. As he complained of heartburn, a mixture containing bicarbonate of soda, bismuth, and eight drops of tincture of nux vomica three times daily was prescribed. (Dr. Lithgow had previously given him three minim doses of liq. strychnin. thrice daily for three or four weeks.) On April 6th Dr. Lithgow wrote that "after some jerkings 12 days ago he discontinued the medicine, but on April 2nd both legs were convulsed and the right arm, with risus sardonicus of right side of face. A squint is said to have been noticed, and there has been a dislike of bright light. Pupils normal. Urine clear, 1015, acid, no albumin." On April 14th I saw him at his home in consultation with Dr. Lithgow, as the attacks of spasm had recurred and double (convergent) squint had been observed. I found that there had been no headache, vomiting, delirium, hallucinations, constipation, or pyrexia. The urine was normal. It was now three weeks since the nux vomica was omitted, yet the spasmodic attacks were more frequent though less severe. The double squint, when it occurred, was convergent. The contact of the stethoscope, also tickling of the sole, made him start. Knee jerks moderately increased; no clonus. Sensation normal. Cough had almost entirely ceased, and the physical signs were very satisfactory. We concluded that the nervous symptoms were not due to strychnine, were not indications of tuberculous meningitis, and were not uræmic. They were obviously the expression of a functional neurosis. Massage was ordered. On April 17th a marked change for the better was reported and the improvement was maintained. On May 6th Dr. Lithgow stated that he was "still improving." In October, 1910, Dr. Lithgow informed me that he was still making progress, but that his nervous tone was not yet normal.

CASE 41.—The patient, aged 23 years, was brought to me by Dr. G. D. Pidcock of Hampstead, on Feb. 7th, 1910. In August, 1909, while on the Continent he had a severe "cold," with coryza and cough, which made him feel "run down." In October slight hæmoptysis occurred; it lasted about a week. The sputum was then examined by Dr. Pidcock, and tubercle bacilli were found. A physician who examined him found no physical signs in his lungs, but advised that in view of the discovery of the bacilli, he should be sent to Ventnor and live as much as possible in the open air. This was done. When I saw him some weeks later there was dullness at all four apices and several other areas, with poor air-entry at the left apex, some crepitus at the right apex and at both lower apices, with a little audible whisper at the left upper apex posteriorly. He was advised to adopt the treatment by continuous antiseptic inhalation, but at first it was very imperfectly carried out, and when I saw him again on March 24th he had lost 4 pounds in weight and all his dull areas were larger, though there was still hardly any cough. He consented to make a more thorough trial of the inhalation method, remained in bed for a fortnight, and wore the inhaler persistently for four weeks. On his third visit, on April 22nd, he had gained 4½ pounds in weight and his physical signs were much improved. On June 18th he stated that there had been no cough or sputum since the last visit, and that he felt quite well. Dr. Pidcock states that when the sputum was last examined it contained "only a few bacilli, and these were all clumped."

CASE 42.—The patient, aged 35 years, unmarried, was seen on Feb. 18th, 1910. She had suffered from "hay-fever" every year for the last three years. Had had "a little cough lately," and a short cough occurred three times during the examination. She was found to have moderate areas of dullness at all four apices and some lower areas, with feeble air-entry, and over the largest dull area (at the right lower apex) there were some tenderness, slight double crepitus, and some prolonged expiration. Under continuous antiseptic inhalation she began at once to improve. On March 11th she had gained 4 pounds in weight in three weeks; all her dull areas were smaller, and the tenderness at the right lower apex had disappeared. She was advised to inhale eight hours daily for four weeks longer. On April 15th she felt better and had gained 3 pounds more (total gain 7 pounds); the cough was now very slight and only before breakfast, and the physical signs were less marked. On May 21st she felt very well, had no cough and no sputum, and her appetite was good. She was advised still to wear her inhaler four hours daily, and all day long if an attack of hay-fever should occur. A letter from her, dated Oct. 11th, 1910, says: "I am still using the inhaler for two or three hours a day; it has been a great boon to me when I have had the beginnings of hay-fever ..... and I wish that so simple a treatment were more widely known."

CASE 43.—The patient, aged 31 years, unmarried, was sent by Dr. Simmons of Westminster on Feb. 25th, 1910. She had had cough more or less for two years, worse for some months. No hæmoptysis. Had lost 6 pounds in weight. A brother died from phthisis at 26, and a sister at 14. Many dull areas were present, the largest being at the right upper and lower apices. Poor air-entry, some prolonged expiration, some crepitus, and audible whisper at the right apex, where cavitation appeared to be developing. She obtained three months' leave of absence from her duties, remained in bed for three weeks, and used the inhaler night and day. I saw her a second time on April 6th; she had gained 4 pounds in the six weeks, all her dull areas were smaller, and the condition of the right apex was much more satisfactory. She came to me a third time on May 13th; she had gained 2½ pounds more, making a total gain of 6½ pounds. She looked well, and her physical signs were further improved, but she still coughed occasionally. She was advised to use the inhaler at night and for six hours daily for three weeks longer; at the end of this time to return to work and practise inhalation three hours every evening and at night.

CASE 44.—The patient, aged 28 years, was brought by Dr. J. L. Forrest of Terrington St. John, Wisbech, on March 23rd, 1910. Four years ago he had pleurisy on the left side. Cough since December, 1909. "Influenza" in February, 1910, after which his cough became worse, and he brought up sputum; this had been found to contain "a considerable number" of tubercle-bacilli. He was very depressed and thought that as he was consumptive he must certainly die. His normal weight was 10 st. 12 lb., but he now weighed only 10 st. 1 lb. Dullness at all four apices (large areas at the right upper and lower apices and at the left lower) and four lower areas. Air-entry practically absent over the dull apices; slight crepitus here and there, but no sign of cavitation. He was advised to remain in bed for two weeks and to practise continuous antiseptic inhalation, and was reassured as to his prospects of recovery. On April 23rd Dr. Forrest wrote: "He is much improved; he put on 7 pounds weight in three weeks, and says he now feels very fit indeed. For ten days the temperature was 99° F. in the evening; now it never exceeds 98·6° in the evening and is 98° in the morning. Cough and expectoration now very slight." On May 4th Dr. Forrest reported: "He had a slight rigor two days ago and the temperature rose to over 100°, so he is to be kept in bed a few days. Sputum examined again; report states that tubercle-bacilli are fewer than six weeks ago." I saw him a second time on May 18th, when I found that he had gained 12½ pounds in eight weeks, all his dull areas were smaller, there was now good air-entry everywhere, but there were some indications of cavitation at the right upper and lower apices (where the largest dull areas were situated). He was advised to use the inhaler not less than six hours daily, and, if possible, at night. He acted on this advice, and when he presented himself for the third time on August 17th I found that in the three months he had gained 2 pounds more (total gain 14½ pounds), that he felt better, and could do more work without fatigue. He complained that his cough was still troublesome for periods of about four days at intervals of about three weeks, and that at these times he brought up yellowish sputum. His dull areas were all much smaller, and the cavities slowly contracting; no active signs. He was advised to persevere. His weight was now 11 st. 1½ lb.

CASE 45.—The patient, a boy, aged 6½ years, was seen at his home in consultation with Dr. J. E. B. Wells of Hoddesdon on April 10th, 1910. At the age of only 11 months a mass of tuberculous glands pressing on the trachea had been removed by operation. He was "a delicate, bright, intelligent child with very carious teeth, poor appetite, cough (worse at night), an evening rise of temperature (which has been twice

followed by profuse sweating), and a morning fall of about 2° F. The sputum has been examined; it contains no bacilli." A linear scar was present on the left side of his neck. A few small cervical glands could be felt. Dullness existed at the left apex in front and at all the characteristic areas posteriorly. Some crepitus could be heard in the left upper lobe and at the angle of the left scapula. The abdomen was normal. It was advised that he should be persuaded to wear a Yeo's inhaler and to practise continuous antiseptic inhalation for a month. On April 28th Dr. Wells wrote that the boy had taken kindly to the inhaler and that he had greatly improved. "Temperature nearly constantly normal for three days; eating well and putting on flesh. The cough is gone, as well as the sweating at night." Three months later (August 9th) he was brought to my house on his way home from Margate, where he had spent ten weeks, and had had no cough during the whole of this time. The characteristic small areas of dullness could still be demonstrated (including now the right apex also), but no morbid sounds.

CASE 46.—The patient, aged 30 years, unmarried, was seen on April 12th, 1910. She had given much time to athletic sports (tennis, hockey, and golf), and won prizes and championships. In 1908 she had influenza and some months later she was found to have dilatation of the heart. This was treated by baths and exercises and recovery followed. She had had a cough for more than a year, and frequently brought up a small amount of sputum, which was often slightly blood-stained. For several months her evening temperature had been 99° F. The sputum had twice been examined for bacilli but none were found. Her weight now was 8 st.; she once weighed 8 st. 9 lb. She thought that she had lost half a stone this winter. Dullness was present at all four apices and some lower areas. Air-entry at apices poor, and slight crepitus could be heard here and there, and at one spot a little prolongation of expiration, but no audible whisper. She was advised to remain in bed for two weeks and to practise continuous antiseptic inhalation. On May 4th she had gained 6 pounds in three weeks, looked and felt better. Her temperature, which had been 99·6° F. at first, gradually fell, and for three days had been normal. Cough better, dull areas smaller, air-entry more free, still a little crepitus. On her way home she caught cold from draughts in the train on a cold day, and her temperature rose to 99°. Yet on June 8th she was still improving, and had gained 4 pounds in weight in five weeks. Total gain, 10 pounds; present weight, 8 st. 10 lb.

CASE 47.—The patient, aged 21 years, was seen at a nursing home in Devonshire-street in consultation with my colleague, Mr. V. Warren Low, F.R.C.S., on April 28th, 1910. He had been admitted into the home under the care of Mr. Low two days before on account of a tuberculous knee, for which he had been under treatment for a considerable period in a large town in the Midlands, and the opinion had been finally expressed by a well-known surgeon that amputation was the only course by which life could be saved. For 11 months he had also suffered from cough, and for the last six weeks the cough had been very distressing. He brought up a copious expectoration, chiefly mucoid. Temperature 102° F. on his admission; it rose to 103°, and was now 101·8°. The right knee was much enlarged and tensely swollen, and was very painful. His cough was frequent, and whenever he coughed an expression of pain was seen on his face, the inflamed knee being jarred by the effort of coughing. His condition was, indeed, most distressing, but Mr. Low had been able to give some relief by the application of a von Bier's elastic bandage round the upper part of the thigh. The patient's condition made it difficult to examine his lungs accurately, but I found that he had large dull areas at all four apices and some lower areas. Crepitus could be heard, especially at the lower apices, but no definite evidence of cavitation. It was advised that he should practise continuous antiseptic inhalation, and be fed freely with milk and malted milk, while the treatment by repeated applications of the elastic bandage (which always gave relief) was continued. Mr. Low and I agreed that in his present condition amputation would be fatal. Under the use of the inhaler the cough was at once relieved, and it almost disappeared within a few days. His knee progressively improved, and after a month (May 24th) he was sent back home with the leg on a splint, and his medical man was requested to continue the employment of the elastic bandage three times a day. In July a little pus was found to be exuding from the outer side of the knee, and a consulting surgeon was called in. His opinion was that the joint was disorganised and full of pus, and that immediate excision or amputation was necessary. Arrangements were to be made for the operation on the next day, but the patient refused to allow anyone but Mr. Low to operate on the joint, so his father brought him up again to the nursing home in Devonshire-street. Here his temperature was found to be 98·6° F., and the chart showed a subnormal temperature during the whole of the last week, including the day on which the surgical opinion was given. The knee was obviously much smaller than in April, it was not tense, or painful, or tender. The small discharging cavity was examined with a probe and found to be separated from the joint. Mr. Low was of opinion that suppuration had occurred in a bursa about the head of the fibula. The patient's general appearance was greatly improved, he was stouter in the face and looked happy and smiling, he was free from pain and had hardly any cough. I found that all his dull areas were much smaller, that there was poor air-entry and slight crepitus at his right apex, and some suspicion of cavitation at his left apex, while the crepitus at his lower apices had disappeared.

On Oct. 16th Mr. Low kindly informed me that this patient is still progressing satisfactorily, that he has no cough at all, and that his temperature has been normal for several months.

CASE 48.—The patient, aged 29 years, was sent by Dr. T. Gash of Rochester on May 17th, 1910. Five years ago he suffered from "pneumonia"; he was in bed for six weeks, and was "tapped twice," a pint of *clear* fluid being withdrawn on each occasion. It can hardly be doubted that this was really a tuberculous attack. In July, 1909, he had "influenza," and Dr. Gash detected evidence of tuberculosis of the lungs and prescribed treatment by continuous antiseptic inhalation in accordance with the recommendation in my paper. (His weight was then 9 st. 13 lb.) He had accordingly used the inhaler for 17–18 hours a day for four and a half weeks. More than a year ago he lost his first child at the age of 11 months from "meningitis." The second baby is now dying from "tuberculous mediastinal glands"; the glands under the jaw were first affected. When I examined this patient he had already gained 4½ pounds in weight. The dull areas in his lungs were very extensive, and there appeared to be cavities at both apices and also at the left lower apex. On June 11th, 1910, he had gained 4½ pounds more, his dull areas were smaller, and his cavities drier; very little crepitus now audible. Hardly any cough. By his own desire he now spent three weeks in Crooksbury Sanatorium, under the care of Dr. F. R. Walters, who kindly permitted him to wear his inhaler for 15 hours every day. On July 11th there was a further gain of 2½ pounds and a further improvement in his physical signs. On Oct. 6th it was found that the cavities were practically healed and very little abnormal sound was heard. Cough and sputum very slight. Total gain in weight 12 pounds. He had not used the inhaler for a month and could do a day's work on his farm without much fatigue.

CASE 49.—A patient, aged 26 years, of Dr. E. B. Randall of Forest Gate, was sent to me on May 23rd, 1910, by a previous patient (Case 38). Dr. Randall wrote: "Her brother, aged 23, died of phthisis six months ago, and she has had a cold and cough on and off since, but came to me with a fresh cold in March, and her cough has continued; there are tubercle-bacilli in her sputum." Her weight was 7 st. 9½ lb. There were rather large dull areas, with double crepitus at the right apex, and inspiratory crepitus at the left. Under treatment by continuous antiseptic inhalation her cough diminished quickly and the sputum became much less. On June 13th she had gained 5 pounds in three weeks, all the dull areas were smaller, much less crepitus was heard, but there were indications of a small cavity at the right apex. She continued to use the inhaler at night and more than eight hours in the daytime. On July 11th she stated that the cough and sputum had nearly disappeared, and there was a further gain of 5 pounds. The physical signs showed further improvement. On Sept. 27th she had gained 6 pounds more, making a total gain of 16 pounds; her weight was now 8 st. 11½ lb. She had had no cough and no sputum for several weeks. Had walked eight miles without fatigue. Had a good colour. Felt and looked exceedingly well. She was full of gratitude for her recovery and said, "I feel I want to tell everybody about it!" She was still in mourning for the brother who had died from the same disease.

CASE 50.—The patient, aged 22 years, was seen at her home in consultation with Dr. H. Tipping of Palmer's Green, on June 7th, 1910. Her cough began in November, 1909, and she was then found to have tubercle bacilli in her sputum. She progressed fairly until four weeks ago, when the cough became worse. She had lost over 7 pounds in weight, had vomited after coughing, and her temperature had been of hectic type—99° to 100° F. in the morning and 102° (twice 103°) in the evening. During the last eight days she had practised continuous antiseptic inhalation, but had renewed the solution on the inhaler only three or four times in the 24 hours; yet the cough had ceased while she wore it. She was found to have rather large areas of dullness, with crepitus, at all four apices, and other dull areas, but no sign of cavitation. She was advised to continue the treatment and to renew the solution on the inhaler regularly every hour during the daytime. I have not seen this patient again, but Dr. Tipping informed me that gradual improvement followed. In about 10 days the temperature fell to 98°–99° (morning) and 100° (evening). Signs of a small cavity developed at the right apex. On July 14th hæmoptysis occurred and lasted for 48 hours, and on the 17th again for 32 hours, then it ceased. Absolute rest was advised. In September Dr. Tipping wrote that she had continued to improve, her lung condition showed an "all-round improvement," but a cavity was still present. She was now walking about quietly. In October she "continues to improve, her weight is increasing; she coughs only at night and in the morning. Is doing light house-work."

The 30 cases reported in my first paper were all incipient or comparatively early cases, though three or four of them were very acute and rapidly advancing when the treatment was instituted. In every one of these 30 cases the result is highly satisfactory. Some of the 20 additional cases now reported came under treatment at a much later stage of the disease or were attended with grave complications. In such instances recovery must be comparatively slow, and the final issue may be doubtful. Any case of pulmonary tuberculosis, if allowed to progress unchecked for many months, may easily reach a condition which is incurable by any form of treatment. But my contention in these two papers is that this ought never to be allowed to happen. Pulmonary tuberculosis is recognisable and ought to be discovered before there is any breaking down of lung tissue. To suspend the diagnosis until tubercle bacilli are detected in the sputum is like delaying the diagnosis of cancer until the glands are involved.

Weymouth-street, W.

HASTINGS WATER-SUPPLY.—The very important question of the water-supply is again before the ratepayers of the borough of Hastings. In February last a majority of 4792 in a poll of 5908 decided against a Bill which the council proposed to take to Parliament, but whereas that Bill included other schemes in addition to the water clauses the present Bill applies only to the Crowhurst valley waterworks, and seeks the usual powers for the purpose of improving and increasing the water-supply. The town council has adopted the Bill by the requisite majority, realising as it does the importance of the matter to the people of Hastings. The demand now exceeds the supply; the storage reservoirs only hold three days' supply, and the works do not possess duplicate machinery. Even if the present Bill is carried through Parliament the year 1915 will be here before the town possesses an additional supply of water.

ON FRACTURES IN THE NEIGHBOURHOOD OF JOINTS.[1]

BY ROBERT JONES, F.R.C.S. EDIN., CH.M. LIVERP.,
HONORARY SURGEON TO THE LIVERPOOL COUNTRY HOSPITAL FOR CHILDREN AND THE ROYAL SOUTHERN HOSPITAL; LECTURER ON ORTHOPÆDIC SURGERY, LIVERPOOL UNIVERSITY.

THE subject selected for this discussion is the management of certain fractures in the immediate neighbourhood of joints. In opening the discussion my remarks will be of a strictly clinical nature and will be based very largely on personal experience and practice. It is a common observation that until quite recently the subject of fractures has remained obscured by reason of the rapid progress made in other departments of our art, and the attraction they prove to most of our able colleagues. Indeed, it is scarcely an exaggeration to say that in many of our hospitals the treatment of a broken bone is left from first to last in the hands of a junior house surgeon. Such delegation of responsibility is often doubtless justified, but I am afraid the house surgeon himself sometimes feels that he is dealing with a comparatively unimportant branch of his art—a feeling engendered by the seeming indifference of his chief.

It is due largely to the brilliant and earnest work of Arbuthnot Lane that our attention has been re-awakened in this subject, and whether we are in agreement with him or not, we must all feel that his strenuous advocacy of his methods has been productive of much that is good.

Every general practitioner is supposed to be able to treat a fracture, but there is now a tendency for our students to be taught to rely too much upon a radiograph for diagnosis; the result of this must mean disaster, and will in some measure account for many stiff and useless joints which so often confront us. The correct interpretation of an X ray photograph amply repays study, but it involves a long and patient education. The radiograph should be used as a court of appeal only after a diagnosis has been attempted, and should not be made to deprive the student of his powers of clinical observation. I would prefer to have a bone skilfully plated in any part of my body by a truly aseptic surgeon rather than that it should be left in the hands of a surgeon, however able, who would treat it in direct violation of mechanical and physiological principles. There really should not exist two schools, one operative and the other mechanical. Each surgeon should decide for himself whether in a particular case an operation should be performed or not, and the way a successful result will be achieved will depend largely upon his special ability. The word "unjustifiable" should be rigorously excluded from our vocabulary when we deal with practices which differ from our own.

During the last 25 years I have treated an unusually large number of fractures involving the function of joints, a goodly proportion of which were not recent and involved disability or deformity, or both. The mere appearance of a joint does not seriously distress a patient; disability invariably does. From the patient's point of view impairment of function is a much more serious deformity than any mere outward change of shape.

I regard every case of fracture as the potential cause of disability, and am still learning from my own mistakes (and sometimes from those of others) certain fundamental rules for clinical guidance. It is necessary, for instance, that we should recognise the importance of Wolff's law, "that the internal structure of bone and then its outward appearance are adapted to the strains to which it is subjected and to the function it performs, and that the structure varies to meet alterations both in strain and function." Normal bone, in fact, is structurally fortified at that point where most work is required of it. By deflecting strain to another part, the structure is correspondingly strengthened there and weakened where it is no longer wanted. The "pathogenesis of deformities is therefore functional." It is therefore necessary in all fractures about joints clearly to appreciate the mechanical function of the joint. What is required is a knowledge not so much of its mere anatomy as of its movements and the directions of the normal lines of strain during muscular exercise.

[1] A paper read before the Surgical Section of the Royal Society of Medicine on Nov. 8th, 1910.

Again, a study should be made of the common disabilities which accompany so-called neglected fractures about joints. In fractures about the shoulder they are deficient abduction and rotation; in the hip, a diminished range of internal rotation, of abduction, and often of extension; in the elbow, fixation at an angle usually of about 130°; in the knee, genu valgum and sometimes flexion. The special deformities or disabilities peculiar to each injury should be studied, anticipated, and avoided.

In case some impairment of function should be feared we should know what particular movement and position of the joint it is most important to preserve, and we should direct the treatment accordingly. As an example I will take the case of a fractured scaphoid. This accident, as we know, occurs very much in the same way as a Colles's fracture. The neck of the scaphoid is usually fractured at its narrow part by a cross strain due to a fall on the hand, which is held more pronated than when a Colles's is produced. The diagnosis even in an early stage is not difficult. Added to the general signs of a sprained wrist there is marked tenderness to slight pressure in the anatomical snuff-box. If such a case is seen early and the wrist be hyper-extended, and be kept in that position for about 14 days, an excellent functional result may be assured. If, on the contrary, it be sent to a masseur with a bias towards strenuous passive movement, a thickened wrist with marked limitation in movement will probably ensue. To those of us who have seen old cases of fracture of the scaphoid the explanation is simple. The main disability consists in a loss of the power of extension. We therefore at once secure our right of way by hyper-extending and fixing the wrist in hyper-extension. The displacement usually occurs during some movement of the hand, and the vigorous masseur often produces displacement of the fragment and traumatic arthritis by exercising his art injudiciously. Again, in the old neglected case of fractured scaphoid or other carpal bone, where the patient appears with a stiff and somewhat flexed wrist, I often apply a club-foot wrench (plate) and fix the hand in hyper-extension. This restores to the patient his firm power of grip which we all lose when our wrist is flexed. I shall have a word or two to say later on the operative treatment of fracture of the scaphoid, but for the moment I am illustrating the value of obviating disability by the anticipation of subsequent events.

Again, as the result of long experience I have formed very definite opinions as to the relative value of passive and active movements, and as these are not quite in accord with prevailing views I will explain them later.

Finally, mere æsthetic considerations of appearance should always be subordinate to questions of restoration of function. In recognition of this principle I always endeavour to preserve a clear right of way free from obstruction by fragments of bone and callus, so that movements of the joint are not impeded, and furthermore to preserve the alignment of bones so that the lines of stress shall fall normally across the joint.

In teaching I constantly emphasise the important rôle of a correct alignment, particularly in the case of the lower limbs. At the ankle-joint it is essential to a good recovery. In fractures about the condyle of the femur it is almost of equal concern. Any deviation from correct alignment means alteration in structure in accordance with Wolff's law—an effort made by Nature to adapt the parts to the deviated lines of muscular stress or to the deviated lines of the force of gravity. These deviations may produce changes identical with those of traumatic osteo-arthritis. A faulty alignment, whether there be end-to-end apposition or not, means erroneous deflection of body weight, a cross straining of the fracture and a stretching of certain structures in the joints which lie above and below the fracture.

I shall scarcely refer to the question of splints. The splint is only a small practical detail compared with the method in which it is used. Inflexible fixation by wire or plate, fixation by splint and bandage, or no fixation, may each be simply good or bad. A surgeon may succeed or fail in any or all of the three methods according as he has or lacks the necessary knowledge and skill. If he has not a clear idea of the precise mechanical effect he wishes to obtain, neither splints, plates, nor massage will avail him.

UPPER EXTREMITIES.

Shoulder.—Coming to definite injuries, I will briefly allude to the so-called fracture of the anatomical neck of the humerus, which most often occurs in old people. It is not always a

genuine fracture through the anatomical neck, but includes both tuberosities in the upper fragment. It is very often impacted, and never requires more by way of treatment than is afforded by a sling and a modest axillary pad. Gentle rubbing may be continued from the time of the accident, but no passive movements should be permitted within less than from two to three weeks. At the end of six weeks the patient usually recovers with an excellent range of movement—a range which allows him to button the back of his collar and reach his brace from behind.

Fracture of the surgical neck requires more care. The head is usually rotated upwards and outwards by muscular action, and if there be much displacement a pull in the abducted direction will elicit crepitus. The ends should be manipulated under extension until a sufficient interlocking occurs so that the head responds to every movement at the elbow. When this is secure the elbow should be pushed towards the shoulder so as to compress the fractured ends, and the arm should be brought down to the side and there fixed for a few days by pad and bandage. At the end of a week it will be found that the spasm of the scapular muscles has passed off and treatment can be continued as in the higher fracture by pad, sling, and bandage.

One of the most common complications of fractures of the upper humerus is dislocation of the head. I have no less than 40 X ray photographs of this condition. I have had the opportunity of seeing the case immediately at the time of accident on several occasions, but more frequently I have not seen them till a later stage. Manipulation should be tried first while the structures are relaxed, and if this fail the arm should be extended perpendicularly while the surgeon manipulates the head. This manœuvre I have found the most successful, and X ray photographs exhibit very clearly the range of movement which followed a reduction by this method where I was assisted by my colleague, Mr. Newbolt. The patient was an old gentleman aged 74, a huge muscular man, and he now possesses an extremely useful shoulder. In a recent case failure to reduce by manipulation should be followed by open operation to replace loose ends. An excellent device to secure this object is that of McBurney, who introduces a hook through a drill hole in the lower end of the dislocated head, whereby, with but little handling of the parts, reduction is effected. The removal of the fragment is always indicated in old cases where nerve or artery is involved. I have been most interested to note the free range of movement which often follows these cases even when neglected. Good rotation inwards and fair abduction have been present in spite of the great deformity.

Elbow.—Fractures about the elbow-joint in children are the source of much trouble to the practitioner, and we have all seen cases of fractures through or above the condyles in which stiffness and limitation of movement have resulted in spite of the most assiduous passive movements begun early and continued late. Medical men have often consulted me with almost the identical story. They say: "For the first week I have treated this supracondylar fracture in exactly the position you advise; the movement seemed quite good and we have regularly applied passive movements once or twice every day and kept the arm at right angles. Instead of becoming more slack this stiff arm is the result." They are astonished when they hear that the stiffness is probably the direct result of passive movement, and that if the arm be slung up and left alone movement will return again. A patient some years ago brought her boy to me with a stiff elbow following a fracture of the epicondyle. Her story was that six weeks previously Dr. A had placed the child's arm in a sling and a week later went for his holiday. The child was then transferred to Dr. B, who immediately began a vigorous campaign of passive movement. Several times a day the arm was flexed, pronated, supinated, and extended, and the ever-growing stiffness was a further stimulus to action. When I saw the child he had a stiff, painful elbow, and the mother, full of indignation, threatened Dr. A with penalties. Dr. B, who was really the unintentional offender, received nothing but praise for his energetic care. I explained to her that both men had done their best and that a third stage of treatment was still needed. The arm was slung up at an acute angle for a fortnight and gradually dropped to a right angle, when active, not passive, movements were allowed, and in less than a month a very considerable range was obtained.

I will now for a moment explain my views as to the erroneous teaching in regard to passive movements. While nothing but good results from early and gentle massage in recent fractures, provided it be applied without moving the parts, great harm often results from combining passive movements with massage at a very early stage of treatment.

I will illustrate this by a case of supracondylar fracture. Such a case, treated either with an angular splint or in the straight position, very often results in limited movement confined in area from the right angle to midway to extension. This is due to faulty alignment, to the obstructive effect of excessive callus exudation in front of the elbow, or to a projection there of the upper fragment of the humerus. The object of the surgeon being to prevent this, he corrects the faulty alignment by acutely flexing the elbow and at the same time secures a right of way before he is opposed by callus exudation. To do this he supinates, then acutely flexes the elbow. For some days it is left in this position and then transferred to a sling, the wrist being kept immediately below the chin. At the end of a fortnight the wrist is dropped two or three inches and the patient is allowed to move the wrist from its resting place back to the chin. If this can be done it may be lowered still further a few days later; if, however, it has stiffened in its new position it requires again to be slung in the more acutely flexed position. At the end of three weeks passive movements may be begun. They should consist of only one movement in each direction (pronation, supination, flexion, and partial extension), and then the arm should be replaced in a sling. This passive movement should be slowly and gently done, the fracture being protected from strain by the surgeon's hand. During the whole of this period massage can be harmlessly and even beneficially practised. Early passive movement, such as is so generally practised, is positively harmful; it disturbs the uniting fragments of bone and leads to fresh plastic effusion, excess of callus, and increased formation of connective tissue about the joint, all of which are conducive to increased stiffness. The oft-repeated to-and-fro movements only do so much daily damage, and no time is given for recovery before a fresh injury is inflicted. I never move such an elbow until I am satisfied that the union is not likely to be disturbed. This is true of all joints. They should be put through each of their movements once and then left to recover from the damage. In one, two, or three days each movement is again repeated, but only once. Passive movements thus applied are comparatively painless and are not followed by rebellious reaction, which is always an indication for continued rest.

Since I have employed the acutely flexed position elbows have ceased to be troublesome. It is very rare to have anything but an excellent result. In the old-standing cases with disability which come to me even now the story usually relates to rectangular splints, pads, bandages, and early movement. The deformities—whether the result of supracondylar fractures, separation and rotation of condyle, or backward dislocation with fracture of the coronoid—are almost always the same. In supracondylar fracture the prominent lower end of the shaft, assisted by new bone, blocks the way to flexion. In separation of the condyle the same kind of obstruction occurs. Callus exudates, bony displacements, and organised effusions oppose flexion, whether the arms are treated by splints in the straight or in the rectangular position.

For over 20 years I have instructed my house surgeons in all cases of fracture and dislocation about the elbow (with the exception of fracture of the olecranon, always easily diagnosed) first to supinate and then acutely to flex the elbow and to fix it in this position. If this advice were generally followed disability would be a rare instead of, as it is, a frequent sequel.

An X-ray screen will demonstrate the effective reduction of the backward dislodgment of the lower fragment in supracondylar fracture. It has been suggested by certain writers who follow this method in separation of the condyles and supracondyloid fractures that the acutely flexed position is liable to produce a forward displacement of the epiphysis. Even if this be so, no harm can come of it, for callus exudation cannot prove obstructive beneath the triceps, and there will be no sharp prominence of the lower end of the shaft to limit flexion.

If the forearm be dislocated backwards we must extend

and supinate and acutely flex, for in this way only can we reduce the dislocation; and should we be unable to flex the arm we may rest assured by such failure that the displacement still remains. If the radius is dislocated forward and inward a similar routine is effective; the supination and extension will reduce the luxation, while acute flexion will maintain the parts in position. If the fracture be intercondyloid the position of acute flexion has this advantage—that it secures for the forearm at once a right of way before exudation of callus and displaced condyles can prove obstructive. It is true that in this particular injury some widening of the condyles is apt to occur when the arm is flexed. The parents should be warned of this, and a very effective way is to ask them which they prefer, an artistic-looking or a mobile elbow. This saves all future complication. Should the injury be separation of the internal epicondyle, there can be no better way to keep it from the common downward displacement than by acute flexion, which relaxes the muscles arising from it.

An interesting and common fracture is that of the head of the radius. It is usually vertical, and occurs within the orbicular ligament. Like all fractures of the upper part of the radius, there is muscular spasm on attempts at supination. There is usually no crepitus, but always distinct pain on direct pressure. In such a case, if supination is obstructed, immediate exsection of the fractured piece is the best treatment. The rough edges should be trimmed, and in order to lessen callus formation, the bare cancellous tissue should be well compressed by means of a smooth steel implement. If the fracture be below the orbicular ligament crepitus is usually obtained, and full supination is effectively secured by the close approximation of the forearm upon the arm.

Fracture of the olecranon I treat by maintaining the arm in the straight position, and, if the line of fracture is transverse and the fragments well apart, I fix the fragments with screw or wire. In oblique or stellate fracture I do not operate. In fractures below the olecranon in the upper ulnar third I have sometimes employed Lane's plates.

I have met with fracture of the coronoid (plate) on several occasions, although recent writers doubt its occurrence. Traumatic myositis ossificans followed this injury in one instance, and this ossific complication is much more frequent than reports would suggest. I have between 40 and 50 radiographs of the condition, and will show you a series of four skiagrams of the same case marking the progress of the disease from the beginning to the end. I have been unsuccessful in my attack upon this disease, as in several instances after operation fresh accumulations of bone have occurred.

Before leaving the subject of injuries to the elbow I would allude to the treatment of old cases of many weeks' or months' duration which come with deformity and disability. The gunstock deformity if extreme can be remedied by supracondylar osteotomy. As a rule, however, no disability accompanies this deformity and operation can only be justified on æsthetic grounds. A far more important class is that where flexion is blocked, and both in old condylar and supracondylar fractures and in old dislocations very useful joints can often be secured. The patient is placed under an anæsthetic and the arm is forcibly flexed until, in spite of all opposition, acute flexion is attained. Mr. H. O. Thomas 20 years ago suggested this in the case of old dislocations of the elbow. It is equally successful in fracture dislocations. By way of illustration we will take the case of a fracture dislocation of some months' standing. We find the elbow at an obtuse angle with about 20 degrees of movement. At anæsthetic is administered and the arm is slowly but forcibly flexed. If this can be done safely at one sitting all the better. Often, however, it is only possible to flex it about 20 or 30 degrees without risk of fracture. The arm is securely slung at the acutest obtainable angle, and in two or three days another effort is made. It is interesting to note that by that time one can quite easily flex it several more degrees. In the most obstinate cases it is not necessary to reduce in more than three stages. It is then slung up for a fortnight and gradually lowered, as I have explained before. In the most unlikely cases a good range of movement often results, and it is well worthy of trial before excision of the joint is decided upon.

Wrist.—I have no new light to throw upon the much-discussed Colles's fracture, and can only very confidently assert my belief in the efficacy of complete reduction. Often no serious effort is made to obliterate deformity, and in no region can one conceive of a greater necessity for it, for exuberant callus must terribly handicap the tendons, both dorsal and palmar.

The text-books still describe the hand-shaking method of reduction with extension, flexion, and ulnar flexion. This indirect method of applying corrective force through a chain of small bones will not appeal to any of us who are in the habit of using the tubercle of our own scaphoid as a fulcrum in forcible manipulations, such as osteoclasis and manual wrenchings. I reduce a Colles's fracture in the following manner. The surgeon with his left hand palm upwards grasps the patient's left arm, placing the tubercle of his own scaphoid against the projecting lower end of the upper fragment; he then places his right hand palm downwards with the tuberosity of the scaphoid on the upper edge of the lower fragment, when, by a forcible pressure, the fragments are powerfully replaced in position and crepitus is often felt. If the reduction be complete the patient can at once move his fingers with less difficulty than before. In old cases of many weeks' standing, when deformity, marked disability, and sometimes pain exists, I place a Thomas's wrench on the lower end of the radius and forcibly reduce the deformity, usually without difficulty. Daily massage, splints for 14 days, and passive movements later, of the kind already described, are the indications in these old neglected cases. In the recent case, early massage, fixation for three weeks, then passive movements, will always result in a mobile hand and wrist. I now experience no difficulties with my cases of Colles's fracture when I treat them in the first instance. The chief cause of stiffness of fingers and wrist is the unreduced backward displacement of the lower fragment, which impedes the action of the extensor tendons while the same displacement interferes with full supination.

I have already referred to fractures of the scaphoid. The method of reduction I adopt is to flex the wrist acutely and place firm pressure on the dorsal fragment, then completely hyper-extend the joint. If this effect cannot be attained, the prominent piece, or even the whole bone, should be excised. The excision is much more successful if performed immediately rather than later. In the old neglected case where the power of grasp is diminished because extension at the wrist is limited, the wrist should be fixed in hyper-extension, even, if necessary, by the aid of the wrench.

LOWER EXTREMITIES.

The hip.—I will only deal with two types of fracture connected with the hip, the one associated with the young and the other with the old. The adolescent fracture is much more common than is generally appreciated, and is productive of the deformity known as traumatic coxa vara. It consists of a partial or complete separation at the epiphysis of the head, a fracture through the neck, or a fracture involving both neck and epiphysis. I will describe for clinical purposes a typical case of separation or partial separation due to a comparatively slight strain. It is of all injuries to the hip the most often overlooked, even by extremely good surgeons; it is furthermore often a serious matter for both the patient and surgeon if an early diagnosis be not made. A boy of perhaps 12 or 14 while playing football attempts to turn suddenly and feels a sharp pain and a disability in his hip. He hobbles off the field and after resting a short time walks back to school and rests. The surgeon is sent for and makes his examination. He finds the movements fairly free in the direction of flexion and extension and adduction; the rotations are distinctly painful, and abduction beyond a short range is not tolerated. The measurements of the limb are normal. Ten days or a fortnight's enforced idleness and the little patient is back to the playground, when simple games are proceeded with. In days or weeks another strain occurs, and further disability, with symptoms no more diagnostic than before. Games are prohibited for the rest of the term, and one day something gives in the hip and he has to be helped to his bed. There may be now a half- or three-quarter inch of shortening, and on examination a separation of the epiphysis, partial or complete, will be found. The case I have given is one I am very familiar with, and it is generally diagnosed as a sprain or as a synovitis. The X ray

photograph shows the femoral head in position and the femoral neck travelling upwards.

In another type the injury is much more severe, the disability more pronounced and lasting, and we find we are dealing either with a fracture of the neck or with a complete separation of the head.

There is a third type which completes the clinical group. A youth slightly injures his hip and is incommoded, hardly disabled, for a day or two. As the weeks pass he complains of an increasing lameness and stiffness at the hip. His symptoms are very much those of a starting hip affection. There is limitation of movement in all directions, shortening of the limb, elevation of the trochanter above Nélaton's line. The X ray shows a coxa vara of the epiphyseal type. The slight injury has partly torn the periosteum and separated the epiphysis, and under the strain of body weight the characteristic deformity occurs. (*a*) From the clinical side I would suggest that a single strain or a succession of strains of the hip-joint in adolescents if followed by disability and pain on abduction denotes an epiphyseal separation. (*b*) If strain completely disables the patient and is accompanied by elevation of the trochanter a fracture of the neck is to be diagnosed. (*c*) If a slight injury is followed by a limp, rigidity, and shortening of the limb we are probably dealing with a coxa vara following a partial epiphyseal separation, but exhibiting signs of traumatic epiphysitis. We must remember that a neglected traumatic coxa vara results in a stiff, adducted, and slightly flexed hip.

The treatment should consist of immediate fixation with extension and extreme abduction. By this means the sliding head or fractured neck is placed in its proper relation with the shaft. Under an anæsthetic the pelvis is fixed while the limb is abducted, so that the upper border of the acetabulum acts as a fulcrum. The patient is then fixed in plaster or, as I prefer, in an abduction frame until consolidation has occurred—probably for about six weeks.

Lest we have to deal with a softened femoral neck a simple calliper splint should be worn for some time, so devised and fitted that no strain upon the yielding femur is allowed while the patient walks.

In fracture of the neck of the femur in the old, several problems confront us, more especially in regard to nursing and in regard to the dangers of pulmonary complications. I am convinced, however, that quite a large proportion of cases, under appropriate mechanical control, make excellent recoveries with but little shortening and comparatively negligible disability.

An interesting question arises in cases of impacted fracture of the neck. Owing to the fact that there may be no shortening, practitioners sometimes hesitate to diagnose a fracture. The presence of external rotation and tenderness about the neck of the femur is sufficient to my mind to determine a diagnosis.

Opinion varies as to the propriety of disimpacting the fracture in those cases. I make a practice of disimpacting in every case where there is any shortening or external rotation of the limb, leaving only those cases in which there is no rotation and little or no shortening. It must be remembered that a patient with an impacted fracture can often lift the limb from the bed, though with more or less pain, and sometimes a correct diagnosis is only arrived at when spontaneous disimpaction occurs two or three weeks after the injury and a consultation is called for It is necessary to emphasise this statement as most authors insist that in no case of fracture of the neck can the limb be lifted from the bed. Cotton, in the latest work published, states, "Uniformly there is inability to raise the leg from the bed," but in a footnote he adds, "I have seen one exception to this rule."

Provided a case is one suited for complete mechanical treatment—i.e., that there exists no condition which renders the recumbent position inadvisable—I endeavour to secure immobilisation and apposition. This can only be done by fixation of the limb in the position of adduction with fixed rather than elastic traction. With elastic traction such as the weight and pulley there must be a sliding of fragments one upon the other when the muscles relax in sleep and on awakening. Liston's long splint and perineal bandage was an attempt to keep the joint at rest. Extension by weight and pulley sought the same end. Fixation by plaster is an advance on either of these plans, but has obvious disadvantages. The splint we use in Liverpool is a modification of the double Thomas's frame, so devised that adduction can be maintained at any desired angle. By its use starting pains never occur, for the pelvis, lower extremity, and splint are all firmly fixed together, and movements of the patient do not alter the tension in relation to the fracture. The patient and the frame are lifted together without in any way disturbing the fracture, and both the frame and patient can be carried together without divorcing the one from the other. This rigidity at the seat of fracture favours repair with a minimum of friction, and thus frees the joint from embarrassing obstacles. In six weeks a Thomas's knee bed-splint is applied with extensions, and passive movement on the lines already indicated are adopted, safeguarded by the splint against a slipping upwards of the femur. A fortnight later and the patient walks in a calliper, so that walking is permitted with no weight-bearing strain on the fracture. During the whole of this time massage is assiduously practised.

In those cases where hypostatic congestion is threatened the patient is placed in a Thomas's knee splint with the limb adducted and she is allowed to be propped up if necessary even in the sitting position. In old cases of fracture with very limited movement and no signs of traumatic arthritis adhesions may be safely broken down under anæsthesia and mobility restored by massage. The greatest care should be exercised in the manipulations. By these methods patients are enabled to walk early without in any way interfering harmfully with the fractured neck.

Split fractures of the shaft of the femur involving the trochanter may need a couple of screws, but nailing the trochanter to the neck in fractures of the aged is undesirable, and many surgeons who have enthusiastically advocated this method are now abandoning it. Good adduction makes for correct alignment, and the trabeculæ of bone laid down in the callus as it becomes hard will follow the normal lines in response to the normal strains placed on the fracture.

The knee-joint.—I treat fractures of the lower end of the femur by means of traction in the line of the limb. This, in my opinion, is best secured by means of a Thomas's knee splint. The backward and downward rotation of the lower fragment due to contraction of the gastrocnemius is of slight importance compared with the effect of upward traction of the quadriceps and hamstrings. This is a doctrine I have taught for many years, and I am pleased to find my opinion confirmed by Cotton in his work just published. The overlapping which we often find depicted by the Roentgen screen is a sliding of the lower fragment in front of the upper fragment. This can always be rectified by powerful traction. From the classical description we would infer that the upper fragment invariably lies in front of the rotated lower fragment, but this is not true in every case. The use of a double inclined plane to neutralise the action of the gastrocnemius is based on a theory which is not found to be true in practice. Our procedure in femoral osteotomy is suggestive in this connexion. In the many thousands of these operations performed, how few surgeons have ever resorted to the double inclined plane? Energetic traction to overcome shortening is the secret of a successful result. The spasm of muscle in any part of the body is very transient and readily yields to pressure and extension. When functional disability results it is usually due to the interference with movements of the patella by the *forward* displacement of the upper fragment.

If there exists as a complication a condyloid separation the displacement may be manually rectified by extension aided by lateral pressure. I have never found it necessary to fix the fragments by nail or screw, although there can, of course, be no objection to this practice. A surgeon obviously must attain his best results by methods he trusts the most. Two conditions, however, are essential to success: (1) Freedom should be secured for movements of the knee; and (2) a correct alignment of hip, knee, and ankle.

Fracture of the internal tuberosity of the tibia is very apt to result in a genu valgum unless a perfect reduction is made. The sartorius, semitendinosus, gracilis, and the internal lateral ligament of the knee run across and support the fragment. If the knee be kept straight and these structures be kept tense they form a most excellent internal splint. The displacement is usually slightly backwards. I have treated a large number of these cases and the results are generally quite good, although sometimes there remains a weakness of the internal ligament. The fracture may be

caused by direct or indirect trauma—indeed, it is not unusual to meet with cases where the injury has occurred solely from lateral strain. If within the first few days one is unable to secure a level intra-articular fracture line, open replacement with nail fixation should be made. I have seen much disability in connexion with these fractures when they have been inefficiently treated.

I have had an exceptional experience in having seen three cases of long-standing fracture of the spine of the tibia, each accompanied by marked interference with function. In the one case, a man of about 40 years was thrown off a bicycle six months previously. He was laid up with severe effusion and was not able fully to extend his knee. When he consulted me, three months later, walking was difficult and recurring effusion took place, although attempts had been made under anæsthesia to straighten the limb by means of manipulation, splint, and bandage, but with no success. He remained unable to extend his knee by about 15°, and a X ray photograph showed a mass of bone in the centre of the joint. On opening the knee by the incision which I adopt for semilunars I came down upon the tibial spine, which was displaced backwards, carrying with it the anterior crucial ligament, but surrounded by a mass of fibrous tissue. I removed the bone, leaving enough adherent fibrous tissue to enable me to fix the anterior crucial. The result is a much stronger and more useful knee, which even yet cannot be fully extended. I cannot remember ever seeing a reference to this injury in literature. A similar case shows the fractured spine lying in front of the joint, preventing extension by purely mechanical means; full restoration of function followed its removal.

Avulsion of the tubercle of the tibia is by no means a rare accident, and I have found it most common between the ages of 12 and 16. It may occur, as in the case of the femoral head, by a single strain or by a series of strains, and it is very apt to be overlooked. The symptoms consist of pain on acute flexion and on pressure, but there is never a complete loss of voluntary extension. When we remember that the tubercle is sometimes part of the main epiphysis, from which a long protuberance descends, that sometimes there is a separate epiphysis and that only a part of the ligament is inserted into it, one can understand the rarity of a complete displacement. It is never necessary to pin this fracture, for in the recent case a pad and splint will completely rectify the trouble. Both in the recent and the older case, a hinge knee-cap limiting flexion is an admirable contrivance. Later the quadriceps must be vigorously massaged. In a few instances I have met with a good deal of thickening and tenderness following these injuries. They occur in those cases where no diagnosis has been made and where the joints have usually been subjected to movements and massage. A linear incision with a chisel into the tubercle in its longitudinal axis acts as a charm, and in a few weeks a disability of some years' standing may be rectified.

Ankle joint.—A volume could be written upon injuries about the ankle-joint, but time will only allow me to refer (and that briefly) to a few of the more interesting fractures that call for special care.

An injury which I have several times met with is a split fracture of the outer portion of the lower and anterior articular surface of the tibia. A triangular piece in juxtaposition to the fibula which may involve only the anterior and external surface of the bone is displaced slightly forwards. This fracture occurs as a separate entity, but is often found in conjunction with a Pott's fracture and sometimes in connexion with a fracture of the astragalus, and then this injury is associated with considerable violence. It is generally produced by a fall upon the foot, such as occurs in the act of jumping. Unless the foot is X rayed the injury is likely to be overlooked and the consequences are anything but pleasant. In the neglected case the patient is unable to flex his foot even to a right angle. He complains of constant pain over the flexure of the ankle, increased on pressure, and the foot has the appearance of being swollen above the instep. There is a pain which catches him across the front of the ankle in walking, just when he is about to change his weight on to the other foot; this is the main ground for complaint. There is a widening of the lower end of the tibia and a forward projection. Indeed, the deformity is suggestive of a displacement backwards of the foot, but a comparison of the heels will at once correct this mistake. The displacement of the fragment is always forwards. If the case be recent, sharp pain is experienced over the slightly prominent lower end of the tibia and the foot cannot be properly flexed. To reduce the fracture the foot should be fully extended, and while firm pressure is made upon the forward fragment the foot should be acutely flexed. If this position be maintained for a few days the deformity will not recur. If the foot cannot be acutely flexed the tendo Achillis should be divided, or if the case falls into sufficiently reliable hands a plate or screw may be applied. In old-standing cases removal of the obstructive bone is required. When operation is refused an addition should be made to the heel of the boot so that the prominent tibia is not subjected to pressure. Even experienced radiographers fail to recognise this condition in old cases, for all that is seen sometimes is a thickening and blurring from osteitis of the lower margin of the front of the tibia. I have described this interesting fracture at length for the benefit of those remote from X ray installations.

The same type of fall upon the foot produces a transverse fracture of the astragalus. The posterior half is displaced backwards and usually lies just in front of the Achilles tendon. The anterior portion may be displaced forwards, but more generally remains *in situ*. The surgeon may at once decide on the wisdom of immediate excision of the displaced half. If one portion of the astragalus remains in position it may be safely left there, and good movement with no shortening may be predicted. After a large experience of the horizontal fractures of the astragalus, both recent and remote, I am biased in favour of immediate removal of the bone. More especially is this the case where it is driven into the os calcis. I regard the mechanical treatment of fracture of the astragalus and os calcis in combination as very unsatisfactory.

I shall only say a few words about Pott's fracture. Although this injury has been a constant source of irritation to both surgeon and patient, I believe it to be very tractable to reasonable treatment. The material deformities in Pott's fractures are two—first, the well-known outward dislocation of the foot, which must be fully corrected; secondly, a less generally recognised slight backward displacement of the foot. Failure to correct this fully is the most frequent cause of the stiffness and limitation of flexion of the ankle which too often follow the injury. All a Pott's fracture requires is really complete reduction, and secondly protection from erroneous deflection of body weight when walking is begun. This concerns the practitioner who first sees the case rather than the consultant. The reduction should be immediate in spite of the swelling and general effusion. Delay adds seriously to the difficulties and prospects. Some surgeons are afraid to exercise enough force. To reduce this fracture I first of all increase the deformity to disentangle the ends, and with the foot somewhat flexed pull the heel forwards and push the tibia backwards until I feel that the dislocation of the astragalus is amended. I then direct all the force that is needed to slightly over-correct the valgus. Unless there is a split fracture of the posterior portion of the tibia there is but little tendency to subsequent displacement, and for three weeks this over-corrected position is maintained. During that period I shall have carefully examined the position of the foot every few days. At the end of three weeks passive movements will be performed in the manner I have already suggested, but no weight-bearing should be done earlier than the fifth week. If the patient, although the position of the foot is perfect, is now allowed to walk without protection he will return to the out-patient department with a valgoid deformity, and herein lies the application of the second principle to which I referred—namely, the correct deflection of body weight. For six weeks or less the patient wears a boot with the heel crooked so that the body weight is deflected from the inside to the outside of the tarsus. If these simple methods are applied Pott's fractures will not prove in the least difficult. Unsatisfactory results are chiefly due to inefficient reduction and indiscriminately applied plaster. If when the case is not seen for a day or two after the injury difficulty is experienced division of the tendo Achillis will materially help the reduction of the displaced astragalus. In lateral deviation of several weeks' standing I have reduced the lateral displacement with a foot wrench, and where that is not available by a simple device which I learnt from

H. O. Thomas. It consists in placing a towel round the patient's heel and the surgeon's shoulders, and another round the lower end of the tibia and the surgeon's foot. When the surgeon endeavours to straighten himself, his thigh muscles pull the patient's tibia down and his shoulders pull the ankle up. After reduction and fixation walking is aided by the foot being kept in inversion by an altered heel and outside iron.

In old malunited cases I operate. If the main deformity is eversion I remove a wedge from the tibia three-fourths through the bone. The fibula is subjected to open osteotomy. The wounds are closed and the stitches removed in a fortnight, when the limb is fractured for purposes of correct alignment. I find it advantageous in this and other fractures and deformities to operate in two stages, so that in my subsequent manipulation I have only a simple fracture to deal with. In old cases of bad eversion and unreduced displacement of the ankle I remove the astragalus and correct the lateral deviation by osteotomy and wedge.

CONCLUSION.

I have given a brief outline of the methods and principles of treatment I employ. They are the result of long practice in a manufacturing and mining district, where I have had exceptional opportunities of seeing a very large number of injuries both immediately after the accident and at a later stage.

Briefly, I pay more attention to function than to appearance, consider correct alignment of more importance than meticulous care in reposition of fragment, believe that pain is always an indication for physiological rest, and therefore deprecate early forced passive movements.

If I prefer methods of manipulation and fixation in some cases where others of my colleagues would prefer an open operation, it is perhaps because for many years an increasing proportion of my work has been the treatment of deformities and disabilities whether of traumatic origin or not, and I have thereby gained confidence in using powerful but carefully graduated force in cases where another would hesitate to do so.

My object has been not so much to discuss various methods of treatment as to expose my own for discussion, and hope that those who follow may do the same for our mutual profit.

Liverpool.

ON THE USE OF POTASSIUM BICHROMATE IN THE TREATMENT OF PHTHISIS.

BY JAMES B. TOMBLESON, B.A., M.B., B.CH. OXON.

I AM glad to report the following six cases of phthisis treated by the internal administration of potassium bichromate.

CASE 1.—The patient was a man, aged 30 years, who had phthisis of four years' duration and who was losing ground. On July 27th his condition was as follows. Weight 129 pounds. Some cough, especially at night, small amount of expectoration containing three tubercle bacilli to a field. Appetite fair. Sleep fair. Right lung: Difficult to say exactly how much disease as the pleura was affected and thickened all over so much that all sounds were very distant. Left lung: Active disease over whole of the upper, and upper part of the lower, lobe, with a cavity at apex. Under treatment improvement was steady until Oct. 30th, when his condition was as follows. Weight 140¼ pounds. No cough. No expectoration. Appetite good. Sleep good. Right lung: No difference. Left lung: Clear except a patch of the size of a half-crown over which a few small crepitations are to be heard. Says he feels quite well, while his wife says that he *is* quite well.

CASE 2.—A woman, aged 27 years. Phthisis of seven years' duration. Had been in many sanatoriums and under all sorts of treatment with little and only transitory benefit, of late getting much worse, till on July 25th she was practically bedridden with condition as follows. Weight 100 pounds. Cough very bad. Much expectoration. Appetite very bad. Sleep poor. Cheeks fallen in. Right lung: Upper and middle lobes, resonance and air-entry much impaired, many moist sounds over whole extent. Left lung: Upper lobe in a similar condition. Under treatment there was steady improvement till on Oct. 30th the condition was as follows: Weight 123 pounds. Cough practically disappeared. Eats and sleeps well. Expectoration down to a third or less. Walks half a mile or more without fatigue. Lungs: A few small crepitations are still to be heard here and there over the front on both sides, nothing at all compared to what existed three months ago.

CASE 3.—A woman, aged 29 years. Phthisis of one year's duration. Condition on Sept. 3rd: Deep-seated disease in both lungs, with varying amount of physical signs. Frequent hæmoptysis, sometimes very severe. Much wasted and weak. Very short of breath, on the point of taking to bed. Under treatment, improvement was slow at first, possibly because she was a nervous woman and suffered a shock from the sudden death of a favourite dog; but it was more rapid afterwards, till on Oct. 30th she was much stronger, walking a fair distance easily; breath much better, hardly any cough, and no hæmoptysis for nearly three weeks.

CASE 4.—A woman, aged 65 years. Had phthisis as a girl, but recovered. Lets lodgings, and towards the end of a heavy season this summer was much run down and gradually became really ill with a bad cough and pronounced wasting. On Sept. 22nd I found her in bed quite convinced that she would never get up again. She was wasted and had a bad cough. She had a patch of dulness with impaired air-entry and many small crepitations on the left side extending from the apex to the third interspace. She was placed under the treatment to be described below. On Oct. 29th she walked up to the surgery to see me, and expressed herself as being much better; her cough was practically gone, her appetite and sleep were normal; she was much stronger, and she had put on a good deal of flesh. On examination her lungs showed no signs of disease, except that the resonance was very slightly impaired in the situation of the old trouble.

CASE 5.—A woman, aged 37 years. Old asthmatic with history of old phthisis, lately getting slowly worse, till she could not get about at all. Her condition on Oct. 1st was as follows. Very weak; could only sit up with difficulty for half an hour; no appetite and little sleep. Cough very bad, with much expectoration. (I did not examine for tubercle bacilli.) On examination I found both apices diseased, such disease extending over the front of both upper lobes. Under treatment her improvement was steady, till on Nov. 2nd I found her in a much improved condition, eating and sleeping better, feeling stronger, with the signs of disease in the lungs decidedly less.

CASE 6.—A woman, aged 23 years, had phthisis nine months and had only recently left a sanatorium; disease apparently progressing steadily. On Oct. 6th I examined her and found both upper lobes diseased, with early signs in the apices of the right middle and left lower lobe. She had a lot of expectoration, occasionally blood-stained, and the nurse in whose charge I found her said that she had as many as seven tubercle bacilli in a field. She had a poor appetite and was weak and listless. Placed under treatment, up to Nov. 1st, when I last saw her, she had rapidly improved both in the condition of her lungs and in general condition.

Of these six patients the last four do not know that they are under any special treatment; and no other medicine than the mixtures mentioned later have been used at any time during the treatment in any of the cases. Improvement has been noticeable after the expiration of the first fortnight of treatment. I am quite aware of the fact that the evidence given above is incomplete, but I hope that it will be sufficient to induce some to try it for themselves.

Now as to the treatment. I give the potassium bichromate in doses of ¼ gr. (2½ minims of a 10 per cent. solution in water) either alone or in a tonic mixture (phosphate, hypophosphite, or simple iron), such dose to be taken in a wineglass of water after food, at first twice and later three times a day. The first dose and possibly the second may cause vomiting, but this does not matter, as, in my experience, toleration is easily established without missing a dose. The colour of some of the mixtures changes from yellow to green, but this seems in no way to impair the efficacy of the mixture.

Westcliff-on-Sea.

TWO CASES OF COMPOUND FRACTURE, WITH TETANIC SYMPTOMS;

RECOVERY AFTER INJECTION OF ANTI-TETANIC SERUM.

BY E. K. WILLIAMS, B.A. CAMB., M.R.C.S. ENG., L.R.C.P. LOND.

I THINK that the interest of these cases is such that they are worth recording.

CASE 1.—The patient, a labourer, aged 53 years, and not a temperate subject, was supposed to have been knocked down or run over by a vehicle in the evening of Dec. 17th, 1909. The patient had no recollection of what happened between 5 P.M.—when he remembered being on the high road—and about 2 A.M. on the following morning. His description of what took place is as follows: "I woke up feeling very cold and stiff with a pain in my right leg; I knew where I was by the side of the road. I got up and felt that my right foot was hurt. However, I was able to walk to a cottage, some quarter of a mile away, where I roused up a man and asked him to allow me to stay in his stable. I opened the door and walked in and lay down on some straw and went to sleep. I was awakened by a man bringing me a cup of tea. I told him that I had hurt my leg and asked him to call my son, who was living in a neighbouring village, that he might bring a cart to take me home." It was not until the patient was being helped into the cart that the injury to the leg was recognised. He was brought to my surgery at 9.30 A.M.

Upon examination I found that the right foot was almost severed from the leg. The lower end of the tibia was shattered, and all that could be made out was a débris of blood, flesh, manure, and road dirt. Although the man was much collapsed immediate amputation was decided upon. He was given 8 ounces of brandy, which improved his condition, and in half an hour he was anæsthetised and I removed the leg 6 inches below the knee. Symptoms of collapse recurring some six hours after the operation another 8 ounces of brandy were given. The patient's condition until Jan. 5th, 1910, was as satisfactory as could be expected, although there was some sloughing of one of the flaps. On Jan. 6th the patient showed symptoms of delirium tremens, and at the same time he complained of stiffness of the jaw and side of the neck. He was unable to rest and took nourishment with difficulty; his pulse was 140 per minute, and the temperature was 102° F., his condition being altogether very critical. Remembering the advice given by Sir Edgecombe Venning in the course of a consultation on a previous occasion regarding the administration of large doses of alcohol in delirium tremens, a considerable dose of neat brandy was administered, with the result that the patient became quiet and was able to get some sleep. Anti-tetanic serum (40 c.c.) was injected into the right flank in the morning of Jan. 7th and 12 hours afterwards another 20 c.c. into the left flank. The muscular spasm, which had now set in, became more frequent and swallowing was difficult, the spasms being more marked in the muscles of the abdomen and the remaining leg. The patient, again showing signs of collapse, was given an ounce of brandy every four hours. On the following day another 40 c.c. of the anti-tetanic serum were injected (20 c.c. in the morning and the same quantity in the evening), with the result that the spasms became less easily excited, but the patient was so collapsed that four ounces of brandy were given and were repeated in two hours' time, and again he was able to get short intervals of sleep. After this no more serum was given. The spasms became gradually less intense and the patient obtained longer intervals of sleep. Liquid food, however, could only be taken three or four times a day, as the attempt to swallow was usually the signal for the "setting" of the muscles of the neck, and it was not until three weeks after the onset of the symptoms that the patient was able to swallow his first piece of solid food. Apart from the fact that there was some slight necrosis of the lower end of the tibia, which necessitated the removal at a later date of a small sequestrum, the patient made a good recovery.

CASE 2.—The patient, a farmer, aged 69 years, fell out of his cart in June last, and was hung up by one leg to some wire-work attached to the body of the cart. The horse took fright, and the patient was dragged about 90 to 100 yards. When I saw him the forearm was nothing but a shapeless mass of manure, road dirt, fleshy pulp, and tiny spiculæ of bone. Immediate amputation being necessary, I removed the forearm just below the elbow-joint, and at the same time injected 20 cubic centimetres of anti-tetanic serum. All went well until the end of the second week, when the patient complained of a sense of stiffness about the neck and jaw. A second injection was then made of anti-tetanic serum, and in three or four days the tetanic symptoms ceased and the patient made a good recovery. I feel sure that the early injection of the serum had a prophylactic action.

Billesdon, Leicester.

OSTEOMYELITIS OF THE LEFT CLAVICLE.

BY ANGUS MACDONALD, M.B., C.M. EDIN., D.P.H. VICT.
HOUSE SURGEON, MACCLESFIELD GENERAL INFIRMARY.

THE literature on this subject is scant and unsatisfactory, and as I have been able to watch a case in all its clinical aspects, perhaps the following facts may be of interest.

A boy, aged 5 years, was admitted to the Macclesfield General Infirmary at 3 P.M. on Friday, April 29th, 1910, manifestly ill. His respirations were 48, his temperature 103·6° F., and his pulse 160. His face was markedly cyanosed, and resembled that of a pneumonic. The history was indefinite. The boy's mother informed me that her son had swallowed a marble. She could not say for certain when this happened, for she had only learnt the fact from the boy on the previous Wednesday when he was first taken ill; but from what he had told her she was of the opinion that it was on the Tuesday that it must have occurred. No other facts could be ascertained.

On admission, a swelling was noticed on the left side of the patient's neck involving the left supra-clavicular, clavicular, and infra-clavicular regions, and the boy kept his head turned rather towards his right side. The swelling was moderate in amount, and the area was slightly hyperæmic as though a poultice had been applied for a short time thereto. It was very tender to the touch, and gave to the fingers a slightly boggy feeling, suggestive of exudation. The percussion note yielded over the said area was dull; auscultation, however, did not reveal any pathological signs. The lungs were next examined, but nothing of clinical importance could be detected. In view of the history of the case an X-ray examination was conducted, but gave no information. I should also add that the blood did not show a leucocytosis, nor did it give the glycogenic reaction. Exploratory needles were inserted over the area of the swelling but were of no avail. The case was discussed, but owing to the conflicting nature of the signs it was recommended to "wait and see," no diagnosis being definitely arrived at. During the same evening the patient's cyanosis increased, his respirations going up to 55. On the next morning (April 30th) the boy developed diarrhœa. His temperature dropped from 103° to 101° and at noon to 99°, his pulse becoming wretched and his face livid and pinched. His respirations went up to 60 in number. Stimulants, including oxygen, were administered, and he revived for two hours; at 3 P.M. he again collapsed, and death took place about 5 o'clock.

A post-mortem examination was made the same evening and the following is a summary of what was found. The child was well developed and well nourished. On incising over the left clavicle the same was found to be stripped of its periosteum, so much so that a single incision on its superior surface allowed the margins of the wound to sag and displayed the shaft. No pus was present, but the bone and its periosteum were separated by a layer of serum about 3 millimetres in diameter. It is interesting to note that the two extremities and joint cavities were unimpaired, the condition stopping short at the capsular ligaments. The bone was of a dirty slaty-blue colour and perfectly smooth. The pleuræ of both lungs were covered by a layer of fibrin 2 millimetres thick. The pleural cavities contained no free fluid, but the membranes were slightly vascularised here and there. On section both lungs showed patchy lobular consolidation. The left apex showed uniform consolidation, this condition having spread directly from the left clavicle. The heart on its pericardial aspect showed typical plastic

pericarditis, with the bread-and-butter appearance. The mitral valves had small vegetations on their surfaces, and showed slight vascularisation at the bases of their cusps. The aortic valves were seemingly unimpaired. Aspiration of bloody serum from the right ventricle yielded a culture of staphylococcus aureus in purity in 18 hours. On a smear on slope agar 4 centimetres long there were 11 colonies.

Of interest in this case are the following points: 1. The misleading history. The fact that the mischief was left-sided suggested to one of the surgeons who saw the case that it might be a mediastinitis consequent to injury to the œsophagus. 2. The absence of any reaction by the hæmic system to combat the situation, inasmuch as the infection was widely disseminated, and there was no leucocytosis or glycogenic reaction, and (post mortem) there was no pus formation. 3. The fulminating character and, above all, the rarity of the lesion.

I must record my gratitude to Mr. J. H. Marsh, honorary surgeon to the infirmary, for permission to publish this interesting case.

Macclesfield.

A CASE OF UTERUS BICORNIS UNICOLLIS.

BY JAMES L. MASTERMAN-WOOD, M.B. EDIN.

THE patient was aged 35 years, married, and has had one child, born in February, 1909. Labour was artificially produced at the seventh month because of the exsanguined condition of the patient owing to repeated severe hæmorrhages which occurred during the fifth, sixth, and seventh months of pregnancy. She suffered regular but slight loss during the first four months of pregnancy. Presentation was normal. At the confinement the patient had a profuse post-partum hæmorrhage to which she nearly succumbed. Eventually she recovered completely, and again became pregnant in November, 1909.

Early in January, 1910, she commenced to bleed rather heavily per vaginam whilst walking, and was immediately ordered to bed. On vaginal examination a complete ovum was found lying in the vagina. It was approximately a six weeks ovum. The cervix was patulous, and bulging through the internal os could be felt a soft elastic mass which was considered to be a second ovum. Under suitable treatment the cervix contracted and the bleeding ceased without the passage of the suspected second ovum.

Early in February she had what she considered was like a rather profuse menstrual period, which necessitated rest in bed for two days. The patient being very anxious to have a second child, and her medical attendant hoping that the second ovum might continue to live, kept her strictly at rest for a considerable time. However, on March 4th she suffered a severe loss again, and I was on the 8th called into consultation over the case. (At this time, it will be noted that, had the pregnancy proceeded, she would have been in the fourth month.) There were no secondary signs of pregnancy. On bimanual examination two tumours, separated by a distinct sulcus but not moving independently of one another, could be felt occupying the position of the uterus. The right tumour seemed to the examining fingers to be a little larger than an ordinary unimpregnated uterus, whilst the left tumour was decidedly smaller. A diagnosis was made of a bicornuate uterus in both horns of which pregnancy had occurred; the left smaller horn had aborted, whilst the right horn retained a missed abortion.

On March 12th I operated. After preliminary dilatation with Hegar's dilators I found, on introduction of the finger through the cervix, two cavities separated by a distinct ridge. The left was very small, but admitted the sound for 1¾ inches. The right cavity was considerably larger and measured 3½ inches. Both cavities were well curetted. The right one contained decidual tissue. The patient made an uneventful recovery, and, except for one rather profuse menstrual period in April, she has menstruated regularly and normally since, and declares that she has never been in better health.

It is with the kind permission of Dr. G. S. Ware that I send these brief notes.

SURGICAL SECTION.

Fractures in the Neighbourhood of Joints.

A MEETING of this section was held on Nov. 8th, Mr. J. WARRINGTON HAWARD being in the chair.

Mr. ROBERT JONES (Liverpool) read a paper on the Treatment of Fractures in the Neighbourhood of Joints, which is printed in full on p. 1479 of this issue of THE LANCET.

Mr. RUSHTON PARKER said that the points to which he desired to draw attention in the manner of dealing with the fractured humerus were the slinging of the arm to the neck and the flexion of the elbow to a more or less acute angle. The adoption of that attitude in any injury between the clavicle and elbow, both inclusive, was of the greatest service in examination and diagnosis as well as in treatment. By that manœuvre the upper limb was bent into two portions, one of which, containing the hand and forearm, was suspended from the neck; the other portion alone was suspended from the shoulder. In fractures of the humerus the injured upper arm was thus at once relieved of the weight and disturbing inconvenience of the forearm, which, when left hanging loose or not specially provided for, caused pain and deformity to the patient and ineffectual devices on the part of the surgeon. In fracture of the lower fourth of the humerus, on account of the invariable tendency to adduction of the condyles under the weight of the elbow, a twist imparted to one of the splints effectually maintained the lower smaller fragment in line with the upper while controlling both. It was needless to add that that manœuvre was only applicable to a splint of sheet metal. In cases of simple fracture it was not difficult, when once the wrist was slung and the elbow bent, and the weight of the forearm removed from the arm, so to apply the splints at the commencement of treatment or by later readjustment as to secure a painless and correct position without hampering the patient's freedom in other respects.

Mr. R. WARREN said that treatment in the neighbourhood of joints might be conveniently divided into (*a*) those which actually involved the cartilage-covered bearing surface of the joint, and (*b*) those which were merely in its vicinity but which might be outside the capsule. A much greater degree of accuracy in replacing the fragments was necessary in group (*a*) than in group (*b*), since open operation would be more often required in the former than in the latter group. Stress was to be laid on the importance of other component parts of the limb beside the base of joints, ligaments, nerves, muscles, &c. Early movement was important in fractures of some joints and was in part an indication for open operation, but only when movement of the joint caused displacement of the fragments. Fractures involving joint surfaces would in adults frequently, in children less often, require open operation even when displacement was small. Attention was directed to the feasibility of moving the shoulder-joint after fracture in 2 to 14 days and massaging from the first. In fractures of the olecranon appreciable separation was frequently absent; a good rule would be to wire or screw those which could not be slung at a right angle without separation occurring. The value of acute flexion in fractures about the elbow was touched on.

Mr. R. H. A. WHITELOCKE said that in all cases of fracture of the patella in which there was much separation the open method of treatment was the only satisfactory one. In consequence of the Workmen's Compensation Act and the Employers' Liability Act the public were no longer satisfied with merely good functional results in the treatment of fractures, and that fact must be accepted in the treatment of fractures in which good anatomical as well as functional results were to be attained in spite of the teaching in some of the text-books. He (Mr. Whitelocke) thought that Mr. Jones had struck the right note when he emphasised the important rôle of a correct alignment, particularly in the case of the lower limbs. He was pleased to hear that

Mr. Jones admitted that there were certain fractures in which open operation was permissible.

The adjourned debate on this subject will be held by the Surgical Section of the Royal Society of Medicine at 15, Cavendish-square, on Tuesday, Nov. 29th, at 5 P.M. Speakers will be limited to ten minutes, and intending speakers are requested to send their names to Mr. Jonathan Hutchinson, 1, Park-crescent, W.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Nov. 11th, Sir A. PEARCE GOULD being in the chair.

Dr. H. BATTY SHAW showed two cases of the Symptomatic Infantilism described by Mr. Hastings Gilford. The first case was that of a female, aged 18 years, height 4 feet 4½ inches (average, 5 feet 1·95 inches), weight 4 stones 1½ pounds (average, 8·2 stones), belonging to a family of normal height and weight. Skiagrams showed that the bony union of the pubis and ischium with the ilium, like a normal individual's, was not complete, but that the union of the great trochanter with the femur, unlike a normal person's at this age, was also incomplete. The patient was clever at needlework, which she carried out at home, earning 4*s.* weekly. She refused "to go to business" with her sisters, preferring to work at home. The delay of growth was first noticed at the third year of life. The expression of the face and the manner of the patient were those of her years but not of her stature. She had never menstruated, and there was no trace of sexual development such as occurs at puberty. The mother had one miscarriage after the birth of this child. From the age of three years the patient suffered for some years with a swollen abdomen and very offensive motions. Dr. Shaw considered that the case was one of intestinal symptomatic infantilism. The second was that of a female, aged 27 years, height 4 feet 6 inches (average 5 feet 2 inches), also belonging to a family the members of which were of normal height and weight. Skiagrams showed that union of the epiphyses of the femur and tibia was not yet complete; at her age they should be. She helped at home, but could not do needlework. She made no progress at school, but had, since her school years, taught herself to read and write at home; she was unable to do responsible work and had a bad memory for recent events. The teeth were defective and the palate was arched. She was a six months child, and at the age of one year was smaller than her newly-born sister. The mother had had no miscarriages. As in the last case, her facial expression and manner generally were more those of a normal individual of her age than of a child of her height. She was not without a fair amount of intelligence, and entered freely into any discussion at home. She had always been very constipated, and up to ten years of age slept 18 hours out of the 24 daily; even now she slept in the daytime a good deal. She began to menstruate at the age of 18, but was not very regular. Though the breasts were not much developed there was the usual development of hair met with at puberty. Dr. Shaw thought that the case was a doubtful one of intestinal symptomatic infantilism. He also showed a case of Asexual Ateleiosis (sub-group of essential or cryptogenetic infantilism of Hastings Gilford). The patient was a male, aged 36 years, height 3 feet 8¾ inches, weight 4 stones 11 pounds 1 ounce, belonging to a family of normal height and weight. Skiagrams showed want of union between the epiphyses and diaphyses of the bones of the hand and forearm. The patient was of good intelligence after a simple childish fashion, such as might be expected of a child with many years of experience. He had worked for the last five and a half years as a compositor, and earned 9*s.* weekly. The delay of growth was first noticed between one and two years of age. In contradistinction to the above two cases the delay of growth and development was much more marked. The external organs of generation were in size and appearance like those of a young child; the testicles were undescended. There was no development of hair upon the face, but the latter showed wrinkling as of age; his manner suggested age, as it was assured, and even a little patronising, to normal adults who had not reached his years. (For full particulars of his condition see Transactions of the Royal Medical and Chirurgical Society, 1902, Vol. LXXV., p. 316, article on Ateleiosis by Mr. Hastings Gilford, to whose courtesy Dr. Batty Shaw is indebted for the use of the case for demonstration.) Dr. Batty Shaw said that, thanks to Mr. Hastings Gilford, something like order had been produced out of the confusion of ideas connected with so-called dwarfs. By dwarfism was meant a condition in which there was defective growth. Development, however, was perfect, and such subjects were simply examples of small men and women; examples might be sporadic or whole races like the various pigmy tribes of the world might occur. Infantilism, however, was quite a different condition: not only was there delay in growth but in development as well, with the result that with diminished stature there existed the defective physical characters or defective mental characters or sexual imperfections. Infantilism might be primary or secondary—i.e., it might be apparently independent of any known cause. The primary cases included cases of ateleiosis (literally "not arriving at perfection") and progeria, two types of infantilism the sharp differentiation of which was entirely due to the efforts of Mr. Hastings Gilford. The cases of ateleiosis showed a curious combination of the features of infancy or childhood with those of more advanced years, whereas cases of progeria showed a mixture of the features of infantilism and senilism. Ateleiosis might be subdivided into two extreme groups; in the one there was full sexual development, though it might have been delayed in appearing; in the other the sexual development was very imperfect, and between these two groups there were others of varying and intermediate stages of development. Dr. Batty Shaw's two cases represented examples of secondary infantilism. The importance and ease of distinguishing between the two types were shown in the following way. Cases of secondary infantilism were dependent upon causes or associated with conditions with which they were all familiar: rickets, syphilis, congenital morbus cordis, micromelia or achondroplasia dystrophia, microcephaly, kyphosis, cretinism, mongolism, intestinal disorders, and even disorders of the pancreas, scarlet fever, typhoid fever, and rheumatic fever. The features of the infantilism in such cases were much less marked than in the primary group, and, moreover, they were not transmissible to succeeding generations. On the other hand, the cases of primary infantilism were dependent upon no known cause, they were very much more marked cases of infantilism, and, as Mr. Hastings Gilford's researches showed, a sexual ateleiotic might beget an asexual ateleiotic child. The contrast between these two groups of infantilism was well shown by the case kindly sent by Mr. Hastings Gilford when compared with his own cases of symptomatic infantilism.

Cases were also exhibited by the following:—Dr. E. FARQUHAR BUZZARD, Dr. ARTHUR LATHAM, Mr. E. L. HUNT, Dr. HERBERT S. FRENCH, Mr. ARTHUR H. EVANS, Dr. JAMES GALLOWAY, Dr. A. E. GARROD, and Dr. A. MANUEL.

SECTION OF ANÆSTHETICS.

Prolonged Anæsthesia maintained by Ether and Gas alternately.

A MEETING of this section was held on Nov. 4th, Mr. RICHARD GILL, Vice-President, being in the chair.

Mr. A. L. FLEMMING communicated a paper on Prolonged Anæsthesia maintained by Ether and Gas alternately. The suggestion that the methods now ordinarily in vogue left room for improvement was based upon the supposition that over-stimulation with ether might contribute largely to some of the post-operative shock occasionally following on certain prolonged and grave operations, especially such as involved the removal of large masses of tissue, as, for example, amputation of limbs, amputation of carcinomatous breasts, and excision of the rectum. Crile and others having noticed that this collapse was less in evidence after nitrous oxide and oxygen than after other anæsthetics, the author of the paper had endeavoured, in a series of 86 more or less grave cases, to diminish the amount of ether used by alternating its exhibition with that of nitrous oxide and oxygen. Although vomiting and nausea were not absent, still they were on the whole less frequent even than after ether, or ether and chloroform; and the general condition, as far as the patient's feelings were concerned, was satisfactory, and in many cases there was no resulting nausea or misery. So far as could be judged from the 86 cases there seemed to be complete absence of any post-operative collapse, but the numbers were

too few to exclude the possibility of coincidence in this respect. Mr. Flemming's object in putting his experience in this method thus early before the section was to suggest that herein possibly lay a means of limiting the extent of ether saturation where it might be considered advisable to do so. For experimental evidence as to the possible evil effects of ether anæsthesia reference was made to Dr. W. D. Halliburton's Croonian lectures of 1901, entitled "The Chemical Side of Nervous Activity"; and to Dr. George Crile's neurocytological studies of the brains of animals under nitrous oxide and oxygen and ether respectively; also to Graham's immunity experiments. As regards technique, the method required a minute attention and concentration, the difficulty being to know exactly when to change from ether to gas, and *vice versâ*. The routine employed in most of the cases here reported was as follows. After inducing by ethyl chloride and ether, anæsthesia was maintained by ether, open or closed, for the first 15 or 20 minutes, until, in fact, the operation was well under way. At this point nitrous oxide and oxygen, with frequent breaths of fresh air, was substituted and continued for a short interval varying in length from three to five minutes, and a change to ether then made, and so on throughout, nitrous oxide anæsthesia being, as is were, superimposed upon ether intoxication; it was generally found that as the operation progressed it became possible to shorten the ether sessions, and to prolong those of nitrous oxide and oxygen. From his experience in these 86 cases the author had come to the conclusion that it was sometimes to the patient's advantage that nitrous oxide had been thus employed so as to lessen the amount of ether toxæmia, and he was satisfied that a perfectly smooth anæsthesia could be maintained by the alternating system, although he felt that with improved apparatus it should be possible to obtain the same result with less changing and chopping. Among the patients who had proved favourable subjects were many for whom nitrous oxide and oxygen alone would not have been suitable, such as alcoholic men, very stout patients, bronchitics, and senile subjects.

Mr. GILL said he had given ether alternately with gas and oxygen for short operations. He was glad to hear that Mr. Flemming laid stress on the limitation of the dose, and also on maintaining the degree of anæsthesia as light as possible.

Dr. J. BLUMFELD had also used these anæsthetics for short operations. He asked whether Mr. Flemming regarded his cases as nitrous oxide or ether anæsthesia? How did he manage to avoid reflex phenomena; if these occurred, did he consider them an indication for ether?

Dr. J. F. W. SILK considered that a very rapid recovery from anæsthesia, as in the case of gas and oxygen, was not wholly an advantage, as the period of analgesia that accompanied recovery from an anæsthetic masked post-operative pain. He thought that severe after-effects usually depended on a uniform level of anæsthesia not having been maintained, and the method advocated by Mr. Flemming would require great skill, and also the use of a very large quantity of nitrous oxide.

Mr. H. E. G. BOYLE inquired why Mr. Flemming induced with ether instead of gas and ether? He considered that a level anæsthesia would be very difficult to maintain with the alternation of the anæsthetics, and that after-sickness would probably be frequent.

Mr. R. W. COLLUM had occasionally used ethyl chloride to deepen ether anæsthesia, as when, for instance, a student allowed a patient to come partially round; these cases had a good deal of after-sickness. He did not see the advantage of alternating the anæsthetics.

Mr. HARVEY HILLIARD had kept records of after-sickness and found it was less frequent when a regulating inhaler was used.

Mrs. DICKINSON BERRY considered that light anæsthesia rather than a necessarily level anæsthesia was one secret of absence of after-effects. She found goitre cases were scarcely ever sick, whether they had chloroform or ether. In these cases a very light anæsthesia was maintained, but it was not level throughout, as at a certain stage they were always allowed to come partially round and strain in order to make sure that the vessels were satisfactorily secured.

Mr FLEMMING, in reply, said that he was surprised himself when he tried the method advocated both by the ease with which a level anæsthesia was maintained and at the satisfactory after-results.

Mr J. F. TREWBY showed a new Inhaler for administering nitrous-oxide gas by the nasal method.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 4th. The new President, Dr. WATSON WILLIAMS, was in the chair, and delivered an opening address, after which

Dr. DAN MCKENZIE exhibited specimens of a Nasal Septum showing Windows. One of the specimens was removed by Dr. Cyril Horsford, the other by Dr. McKenzie. They were interesting for two reasons: first, because the presence of a window in the septal cartilage, with intact mucous membrane, rendered the operation of submucous resection more difficult, unless the possibility of this condition were remembered; secondly, because the spontaneous production of septal perforation from ulceration was favoured by the presence of such windows. In Dr. McKenzie's experience, acute perforating ulcer of the nasal septum penetrating not only mucous membrane but also cartilage was extremely rare. As to the cause of these windows the opinions generally seemed to be that they were sometimes developmental and at other times were induced by the long-continued bilateral pressure upon the cartilage of mucous scales or crusts.

Mr. HAROLD BARWELL showed a case of Subglottic Stenosis after Tracheotomy.

Dr. STCLAIR THOMSON showed a case of Scleroma of the Naso-pharynx in a Polish woman.

Dr. G. WILLIAM HILL exhibited a case of Carcinoma of the Œsophagus in which the dysphagia was treated by a new form of intubation apparatus. The patient was a man aged 49 years, with a history of five months' dysphagia. Much frothy mucus was expectorated, and there were present cough and abductor paralysis. Œsophagoscopy showed fungating growths on the anterior and posterior wall. There was a tight stricture 28 centimetres from the teeth; a portion was removed for microscopy (epithelioma). After great difficulty and delay the stricture was threaded and dilated up by graduated bougieing, and Dr. Hill's styletted modification of Symonds's long rubber intubation apparatus was inserted. The patient was at first fed entirely through the tube, but could now swallow soft food beside it; the mucorrhœa also was much less and the patient was not so asthenic. The disease was considered too advanced and the actual strictured area too long for radium treatment, but the method of permanent intubation employed did away with the necessity of resorting to gastrostomy. The apparatus, with its dental attachment, was also exhibited.

Dr. W. JOBSON HORNE showed a case of "Dents de Scie" of the Vocal Cords.

Dr. H. W. FITZGERALD POWELL and Dr. G. W. BADGEROW showed a case of Tumour of the Post-nasal Space which had been exhibited at the previous meeting. The patient was a man aged 27 years. A tumour of the post-nasal space was pushing the soft palate forward and involving the palate; it was growing from the lateral walls of the naso-pharynx and infiltrating the lining of the same, and it extended down to the tonsil, which it involved. It was removed by operation, along with the portion of palate involved and the tonsil. Good recovery followed. An obturator closing the opening (fitted by Dr. J. W. Pare) was employed, and there was no recurrence.

Mr. C. A. PARKER exhibited a Tonsillolith in the left supra-tonsillar fossa.

Dr. BADGEROW showed a case of Small Tumour of the Soft Palate.

Mr. W. G. SPENCER showed a case of Lingual Thyroid.

Mr. T. JEFFERSON FAULDER exhibited a case for Diagnosis. The patient, a female, aged 23 years, had a swelling at the left side of the nose and the inner canthus of the left eye. It first attracted her attention about three years ago by causing pain. She now had intermittent headache and, on stooping, felt giddy. She suffered from nasal obstruction; the mouth was always dry and offensive in the morning, when she would cough up some "phlegm and bad blood." This condition would improve during the day. There were no occular symptoms except some epiphora and irritation. The swelling in the left inner canthus and the outward displacement of the left eye were easily seen. The swelling corresponded in position to the lamina papyracea of the ethmoid bone and the tendo oculi was stretched across its front. It was hard, rounded, sessile, and slightly tender. There was a swelling of similar character in the antero-superior part of the left nostril. The

post-nasal space was normal in all respects except for dryness of the mucosa. Transillumination of the antra was equal and remarkably bright; of frontal sinuses it was negative, or, if anything, somewhat against the right sinus. With the case were shown (*a*) photographs of the patient at the ages of 6 months and 15 years, both showing asymmetry of the orbits; (*b*) skiagrams; and (*c*) an orbito-nasal (ethmoidal) exostosis removed from a female patient, aged 20 years, who had proptosis, diplopia, and defective vision (3/60) of the right eye, as well as right nasal obstruction. The tumour was visible in the naso-pharynx, blocked up the right nostril, and was shown by skiagrams to extend in the orbit as far back as the optic foramen. It consisted of cancellous bone with a covering of dense eburnated bone. This patient has recovered her vision and remained well ten months after operation.

Dr. NOEL D. BARDSWELL showed a case for Diagnosis.

Dr. HORSFORD showed a case of Aphonia for Diagnosis.

The PRESIDENT exhibited a Laryngeal case.

Dr. F. F. MUECKE showed a man with Paralysis of the Internal Tensors.

Dr. J. DONELAN showed a man with a Fistulous Opening into the Maxillary Antrum.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Chronic Endometritis.

A GENERAL meeting of this section was held on Nov. 3rd, Dr. H. MACNAUGHTON JONES, the President, being in the chair.

The PRESIDENT referred to the great loss which the section had sustained through the death of Dr. J. J. Macan. He had attended the council meeting in October, and had been present at the opening meeting of the session. Dr. Macan had held a prominent place in the literature of obstetrics and gynæcology in this country for over 20 years. He edited the *Journal of the British Gynæcological Society* for several years, and his comprehensive quarterly summary of current international literature was not excelled in any cognate journal in any language. With a genial, generous-hearted, and kindly disposition, outspoken, ruggedly honest in his praise or criticism, there was a striking personality which would live in the affection and memory of all those members of the section who knew him and admired his abilities.

Dr. ARCHIBALD DONALD and Dr. W. FLETCHER SHAW read a paper on the Symptoms and Treatment of Chronic Endometritis, with Special Reference to the Results of Curetting. The paper dealt with the clinical aspects of chronic endometritis. The name was used to denote a class of cases of which the commoner symptoms were menorrhagia, metrorrhagia, leucorrhœa, dysmenorrhœa, and pain in the lower abdomen, associated with a moderately enlarged uterus which was tender on palpation. Two groups of cases were included under the name: in one an inflammatory change seemed possible; in the other any inflammation of a septic or specific origin seemed out of the question. So far little help had been forthcoming from the pathologist as to the changes in the endometrium which were associated with these symptoms. Dr. Donald and Dr. Shaw continued to use the name "chronic endometritis" as a matter of convenience, although real inflammation of a chronic kind was probably rare. The objects of the inquiry were to ascertain the results of curetting and the comparison of the results in the different types of case, and further to find out the relative frequency of the various symptoms and the result of treatment in each individual symptom. The clinical material consisted of 267 cases (hospital and private) of uncomplicated chronic endometritis. Notes had been taken before treatment in all of these cases, and the later condition of the patient was ascertained by written replies to printed questions. In all cases at least 12 months had elapsed since the operation. An analysis of the symptoms and their relative frequency showed that menorrhagia, dysmenorrhœa, and leucorrhœa were most frequent in all cases, menorrhagia and leucorrhœa being most frequent in women who had had children, and dysmenorrhœa in nulliparæ and virgins. Notes were made as to the position of the uterus in 188 cases, and it was found that anteflexion was twice as common as retroflexion in virgins, while in women who had borne children these conditions were reversed. As to the effects of treatment, the general result was that of the 267 patients 230 (or 86·1 per cent.) were relieved, and 37 (or 13·9 per cent.) were not relieved. The large majority did not obtain the full benefit until some months after the operation. Particulars were given in detail as to the results in regard to the various symptoms. In dysmenorrhœa the results were very good and went to confirm the belief that this symptom was often caused by some abnormal condition of the endometrium. Leucorrhœa was not quite as amenable to treatment, although the results were fairly good. Attention was directed to the point that the leucorrhœal discharge in the cases under consideration was always of uterine and not of vaginal origin. For the chronic abdominal pain and also for metrorrhagia the treatment was very successful. Some observations were made on the position of the uterus, and the results of curetting alone in cases in which the uterus was retroflexed or retroverted were found to be rather better than in the cases in which the uterus was anteflexed or anteverted. The effect of curetting in cases of sterility was distinctly good; in nearly one-third of the cases pregnancy followed within a comparatively short period.

OTOLOGICAL SECTION.

Syphilis in Relation to Otology.

A MEETING of this section was held on Oct. 25th, Mr. ARTHUR H. CHEATLE, the President, being in the chair.

After a few introductory remarks, in which he thanked Dr. E. Law for the very able manner in which he had carried out the duties of president during the preceding year, Mr. Cheatle referred to the arrangements for the section during the coming session. He announced that six meetings would be held instead of four, and that possibly in addition there might be an extra-metropolitan one at Bristol. He also announced that the meeting on March 17th, 1911, had been set apart for a general discussion, the subject chosen by the council being Trauma in Relation to Otology, to which it was hoped that members of the Surgical Section would come.

The PRESIDENT then opened a discussion on Syphilis in Relation to Otology. He divided the subject into cases due to (1) congenital and (2) acquired syphilis, and then proceeded to subdivide them according as to whether the external ear, the middle-ear tract, or the perceptive portion of the ear was involved. In speaking of the congenital cases he laid special stress on the importance of Wassermann's test for the diagnosis, and in reference to the treatment he pointed out that he had generally found the usual anti-syphilitic remedies useless, but hoped that better results might be obtained from Ehrlich's "606." He also mentioned that in these cases he had obtained great benefit from the use of blisters applied to the mastoid. In dealing with cases of middle-ear deafness in acquired syphilis, he laid great emphasis on the importance of examining the naso-pharynx for gummata, and also pointed out the difficulty of exactly localising the seat of the lesion when the perceptive portion of the ear was involved owing to the absence of post-mortem examinations in such cases. The various forms of disease were illustrated by cases that had come under his own observation.

Dr. URBAN PRITCHARD stated that he was glad to hear the President's allusion to the fact that in congenital syphilis the age was not always a fixed one; he had seen cases which came on quite late in life, and occasionally the keratitis came on after the internal ear symptoms; he had himself had excellent results from blistering. In regard to acquired syphilis, he had been struck with the infrequency of Eustachian deafness in syphilitic pharyngitis, and in cases of secondary or tertiary affections of the meatus he pointed out that it was very easy to make a mistake in thinking that the condition was epithelioma.

Mr. C. E. WEST asked if there was any definite proof in the late cases of labyrinthine trouble of the patient being syphilitic, and even if the patient was syphilitic as a child, that the later deafness was due to syphilis. He mentioned that he had never seen a case of chancre of the Eustachian tube, but that a collection made in 1885 gave 100 cases, many of them reported in France; he thought that the increasing use of sterilisers coincided with their disappearance. In regard to condylomata, he had been struck with the intense pain the patients suffered.

Mr. A. L. WHITEHEAD stated that as a point of diagnosis he had always regarded the chronic painless effusion of the

knee-joint as a valuable sign. With regard to ulceration of the nose and nasopharynx in congenital conditions, he did not think this was infrequent; he thought that the point was not sufficiently emphasised that in congenital syphilis there might be double lesions. With regard to condylomata in the acquired condition, he agreed with Mr. West as to the pain that was present, and pointed out that though intractable, as a rule they healed without causing contraction.

Mr. P. MACLEOD YEARSLEY said he would like to disagree with the President on one part of his paper—viz., that in which he said that the disease never caused lesions in utero such as to produce deaf-mutism; he did not think that that statement was proved, as Bardeau described his researches on stillborn children who were syphilitic, and he found the middle and internal ear involved, chiefly purulent middle-ear inflammation with adhesions of the membrane and hæmorrhages and accumulations of pus in the labyrinth with destruction of the organ of Corti. He thought it possible that syphilis might cause deafness in utero. He agreed that otosclerosis was not due to syphilis.

Dr. DAN MCKENZIE pointed out that syphilitic deafness might come on when the patient was under antisyphilitic treatment, and related a case illustrating this point. With regard to the pathology of the congenital cases, he agreed with Mr. Yearsley and remarked that a paper had appeared in the Archives of a German society which dealt with cases of stillborn children from syphilis. On microscopic examination these children were found to have distinct lesions, probably of a meningeal character, consisting of round-celled infiltration, and there were other pathological changes which, if these children had lived, would probably have caused deafness. With regard to the vestibular test, he remembered testing a few congenital cases in one of which the vestibular reactions were normal, but in most of those tested the vestibular reactions were absent in proportion to the deafness.

Mr. J. E. R. MCDONAGH did not think one could gauge the effect of treatment in congenital syphilis, because, irrespective of treatment, congenital syphilis tended to give a positive Wassermann reaction throughout life, and that was not altered however much mercury was given. That positive reaction should not be taken as an indication that the "606" had no effect on the Wassermann reaction in congenital syphilis. In late acquired syphilis one could change the reaction by giving "606." He had treated only one case of ear trouble with "606," and that was an acquired case in which the patient had a lesion of the ninth nerve on one side. He had reported the case in THE LANCET.[1] Hearing was certainly improved after the injection. With regard to eye troubles after the injection, Ehrlich had had 12,000 reports without any eye trouble. He himself had injected 82 patients and there had been no eye trouble; two of them had optic neuritis, but it cleared after the injection. In answer to Mr. SIDNEY SCOTT, he said that in congenital syphilis, if one got a negative Wassermann test one could be fairly certain the case was not congenital syphilis. In acquired syphilis that did not always hold good; there was a small percentage who had got syphilis but who gave a negative Wassermann reaction.

Mr. E. B. WAGGETT referred to the importance of examining the post-nasal space in patients who had otalgia with syphilis. He asked the President as regards his experience of suppuration in the middle ear in cases of tertiary syphilis; he had himself seen a few cases.

The PRESIDENT, in his reply, said he had come to learn and he had learnt. He had already expressed his ignorance of some of the points about which he had been questioned. As to the proof of the cases being syphilis, he had taken every care to exclude everything else, but most of the cases were seen before the Wassermann test was in vogue. The keratitis frequently preceded the ear trouble, and he thought it was more frequent than was generally supposed. With regard to middle-ear affection in congenital syphilis, apart from Eustachian obstruction met with in nasal disease, he did not think there was such a thing as congenital syphilis causing what would appear to be catarrh of the middle ear, producing changes in the membrane. It was curious that condylomata did not cause contraction. He was glad to hear Mr. McDonagh's remarks, and it was clear that much experience was necessary in order to place the matter on a sound basis.

[1] THE LANCET, Oct. 22nd, 1910, p. 1200.

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL evening of this society was held at the Medical Society's rooms, Chandos-street, W., on Nov. 10th, under the chairmanship of Mr. GUSTAVUS HARTRIDGE, Vice-President.

Mr. G. WINFIELD ROLL showed a case of Sympathetic Ophthalmitis which had recovered. The patient was a boy who had his cornea wounded by a jagged piece of china, and sympathetic ophthalmia ensued six weeks from the original injury. Atropine and hot fomentations were applied, and mercury was given internally. He had now 6/12 vision in the sympathising eye, while vision in the eye originally injured was 6/36. No intra-ocular injections had been used.

Mr. GEORGE COATS showed a series of slides illustrating Atypical Coloboma of the Iris and Lens, with persistent mesoblastic strand. The case, he contended, favoured the theory of Hess—that coloboma of the lens was due to fibrous strands of that sort. Not only the vitreous and the retina showed changes, but the choroid also. It favoured the theory that atypical coloboma was due to pressure on the back of the eye of such persistent strands when the lens almost filled the globe. In the upper part of the eye there were certain areas of choroidal atrophy, although there was no persistent mesoblast. If found alone they would be taken for patches of old choroiditis, thus illustrating the difficulty which often arose in differentiating between a congenital abnormality and a patch of inflammation. That difficulty had given rise to the idea that true coloboma did not occur in the macula, whereas Mr. Coats thought it did. The changes in the fundus exactly followed the retinal vessels. Another interesting point was in connexion with the development of zonula; he favoured the mesoblastic origin. The cases upon which he based his remarks were mostly cases of aniridia.

Mr. W. H. H. JESSOP showed a case of Recurrent Melanotic Sarcoma of the Conjunctiva which was shown before the society seven years ago. At that date the tumour, but not the eye, was removed, and proved to be melanotic sarcoma. There was a recurrence in 1904, up to which time it had remained quiet, and there were only a few brown pigment spots. It was wandering pigment. In May, 1907, there was more congestion and then another swelling at the site of the old one. That recurrence was removed and the site cauterised. The patient came again in November, 1910, having had no pain and with vision 6/9, there being a small swelling under the upper lid. It was removed with the surrounding conjunctiva and found again to be melanotic sarcoma. Nothing more was now to be seen except two little patches. He had never seen a case of the kind last so long with such slight recurrences.—Mr. HARTRIDGE commented on the possibility of being more conservative with eyes the seat of such tumours.—Mr. E. TREACHER COLLINS alluded to three cases of epibulbar sarcoma which he had removed without taking away the eye, and there had been no recurrence, one of them having been done 20 years ago, and she had had the growth partly removed before he saw her. But that was not a melanotic growth but was definite sarcoma, as confirmed by Mr. Butlin.—Mr. E. W. BREWERTON believed that in Mr. Jessop's case the outlook was now less hopeful, and that a general metastasis was setting in, which would kill the patient. Something more should, he urged, now be done to the conjunctiva, and the brown pigment patches should be excised.

Mr. JESSOP also showed a case of Solitary Tubercle of the Choroid, in which there had been no vitreous opacities and very little pigmentation. The condition now looked like retinitis proliferans.

Mr. J. H. TOMLINSON showed a simple Projecting Polariscope for use in Testing Colour-perception, and illustrated it with a patient whose illumination perception was normal but colour-vision abnormal.

Dr. JOHN HERN showed a case of Kerato-irido-cyclitis. This condition he regarded as a clinical entity. The causation had puzzled him, but some of the patients had been syphilitic. In treatment he insisted on the value of peritomy, getting right down on the sclera by means of a small curette, to destroy the blood-vessels on the surface of the sclerotic. He usually tried treating such cases with mercury first.

Mr. N. BISHOP HARMAN showed Twin Scissors for Sclerotomy (Herbert's operation), which worked like a punch, but without punching anything out.

Mr. R. FOSTER MOORE showed three cases of Severe Loss of Sight following Hæmorrhage. One was hæmorrhage after miscarriage, another hæmatemesis, and the third prolonged bleeding from the eye.

Mr. H. E. JULER showed a case of Sarcoma of the Iris, the interest of which was that it might be cyst.—Mr. TREACHER COLLINS said the case was under his care, having been sent to him by Mr. H. H. Taylor of Brighton. He advised him, before sending the case up, to puncture it; that was done, but nothing escaped, and there was no alteration in the appearance of the tumour. He had been expecting to see the case.

Mr. F. HEWKLEY showed a case of Injury to the Eye. It was a degenerate eye, the sight having been lost during the last nine years.

Mr. R. R. CRUISE showed a case with Fibrous Mass over the Disc, which he believed to be the result of injury. There might have been a coloboma in the region of the nerve towards the lamina cribrosa, and the coloboma might have filled up with clot.—Mr. COATS believed it to be due to rupture of the nerve, but Mr. M. S. MAYOU took another view regarding the history of injury as simply a coincidence.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 11th, Dr. W. G. Willoughby, the President, being in the chair.—Mr. A. W. Gant (borough dentist, Cambridge) introduced a discussion upon School Dentistry. After drawing attention to the great differences in the figures as to carious teeth which were to be found in the reports of school medical officers, he expressed the opinion that at least 90 per cent. of the children attending public elementary schools in this country had dental caries. He urged a more careful examination for the discovery of caries than it was practicable for a medical inspector to make. It was very necessary to discover the earliest traces of caries in the permanent teeth, and if the future well-being of the children had to be considered as well as the immediate present the ages for medical examination and re-examination would not suit dental investigations. In examinations where no treatment was going to be offered, and when advice was sent to parents only in extreme cases, the most suitable plan would be to make a primary division between the temporary and the permanent teeth. The temporary teeth could then be divided into three classes, signifying fair, bad, and very bad dentures, or the subdivisions for the permanent dentition could apply to this also. The children with permanent teeth should be divided into those whose teeth were fairly efficient, those whose grinding capacity was impaired on one side only, and those whose grinding capacity was impaired on both sides. The present system of noting the number of carious teeth at the best could only make a very imperfect division of the children and gave little guide as to how the function of mastication was being performed. A phase of inspection which Mr. Gant considered of great importance from a medical point of view was the presence of pus in the mouth, which could invariably be traced to its source at the roots of one or more teeth. He had found over 30 per cent. of the children he examined with pus discharging from septic teeth, and about 5 per cent. of these had oral sepsis in a most marked and dangerous degree. He considered it was indispensable that any dental treatment offered to school children should be related to the school medical service as a whole, and that the preliminary steps which must be taken with regard to dental treatment should rest with the school medical officer. He had little hope that the mere cleansing of teeth, however regularly done, would abolish dental caries. Nevertheless, it was certain that cleanliness in that direction would have an appreciable effect provided it could be practised from the time the first teeth appeared. Very little good could be expected from persuading the present-day elder children to use a tooth-brush, but efforts should be made towards teaching the "cult of the tooth-brush," more especially in the infant schools.—Dr. H Cooper Pattin said that in Norwich, contrary to the experience elsewhere, the parents appeared to be really anxious that their children should have dental treatment.—Dr. R. E. Lauder considered it was futile to expect parents to take their children to a dentist if they had to pay for the treatment, and he urged that preventive measures should precede treatment.—Mr. R. Denison Pedley expressed the opinion that the appointment of a school dental surgeon was one of the most important parts of preventive work. There was an enormous amount of preventive work to be done, but it was useless to expect parents to realise their responsibilities unless they had some knowledge of the necessity for treatment, and that knowledge should come through the teachers, who should be given an opportunity of gaining an elementary knowledge of dental work. The school medical officer as a rule knew little or nothing about the teeth owing to the fact, which was to be deplored, that conservative dental work was not carried out in general hospitals.—Dr. Andrew J. Laird referred to the desirability of the dental inspections being made by dentists, and preferably by those who would subsequently carry out the treatment. He advocated the early use of the tooth-brush, and if possible before school age.—Dr. A. H. Bygott declared that the best teeth among the poorer classes were to be found among those who came under the care of boards of guardians, and thought it a great pity that a child had to be a pauper before its teeth could be good. He did not consider the tooth-brush was so necessary as some persons had stated.—Dr. Sidney Davies urged the importance of educating people in the proper methods of feeding, and thought that dentists might render assistance in recommending a practical diet which as far as the teeth were concerned would be self-cleansing.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—A meeting of this society was held on Oct. 7th, Professor R. Muir, the President, being in the chair.—The President reviewed briefly the chief stages of research which had led up to the discovery of the Wassermann reaction.—Dr. C. H. Browning explained in detail the method of the reaction, and stated that at present there was no possibility of the test being satisfactorily carried out except in specially equipped laboratories by experienced workers. As to the specificity of the reaction, positive results had been obtained in other protozoal diseases besides syphilis (frambœsia, sleeping sickness), and in leprosy of the tuberous type. Except in these conditions positive results were very rarely obtained with non-syphilitic sera. In untreated acquired syphilis the Wassermann reaction was present only exceptionally before, and usually from 15 to 30 days after the appearance of the chancre. In the secondary stage 95 per cent. of cases, and in the tertiary stage 75 per cent., were positive. Of cases in which the disease had passed into a latent stage 50 per cent. reacted positively, and a similar percentage of positive results had been obtained in women who had, in accordance with the law of Colles, borne syphilitic children without themselves exhibiting symptoms of the disease. No limit could be set to the date after infection at which a positive reaction might be obtained; cases had been found to react positively 40 or 50 years after the original inoculation. The clinical significance of a positive reaction was that it indicated that dissemination of the virus had occurred and that the living virus was probably still present, though not necessarily infective; tertiary lesions, for example, were usually non-infective on account apparently of the small number of spirochætæ which they contained. The diagnostic value of the reaction was evident in determining the specific nature of atypical lesions—e.g., apparently non-syphilitic soft sores, of extra-genital sores, and of manifestations of the disease in cases where primary and secondary symptoms had been suppressed. As a means of diagnosis the reaction was supplementary to the examination for spirochætæ, and where these were scanty, as in tertiary lesions, it was alone available. It had also shown the syphilitic nature of cases of primary aortic disease, of leukoplakia, and of various cerebral lesions. As to the effect of treatment on the Wassermann reaction, the general result was that energetic mercurialisation early begun and long continued restored the serum to its normal condition, and only by such treatment could late manifestations be prevented. Treatment should also be adopted in latent cases giving a positive reaction, in view of their tendency to relapse and of their infectivity. In all cases treatment should be continued as energetically as possible for a prolonged period after the disappearance of all symptoms, including the Wassermann reaction. Thereafter at intervals repeated tests should be made, and the reappearance of a positive reaction should indicate the necessity for immediate resumption of treatment.—Dr. Ivy Mackenzie referred to the observations of Dr. W. Gilmour of Gartloch Asylum, who obtained a positive Wassermann reaction with the blood of 98 per cent.

of 180 cases of general paralysis, and of 70 per cent. of 22 cases of locomotor ataxia. The cerebro-spinal fluid gave a positive reaction in 40 out of 68 cases of general paralysis, and in two out of six cases of locomotor ataxia. Referring to dioxydiamidoarsenobenzol she gave details regarding the drug, methods of administration, dosage, effects and excretion. In nine cases of recent syphilis in Maryhill Barracks the injection of one dose had immediately beneficial effects, the patients being dismissed from hospital within a fortnight free from any evidence of disease. Of 16 cases of general paralysis treated with "No. 606" four were undoubtedly benefited. From being restless, stupid, dirty in habits and difficult to manage, they had become sensible, quiet, intelligently interested in their surroundings, and able to work in the wards on their own initiative. In two of them there was a marked retrogression of the physical signs, and one patient was ready for dismissal.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 10th, Dr. T. R. Bradshaw, the President, being in the chair.—Dr. Hubert Armstrong showed two babies, aged 5 and 7 months respectively, with Obliquity of the Cranium due to suckling at one breast only, and read a note on Cranial Asymmetry in Infants due to Postural Causes. Special reference was made to the mechanical causation of the rickety head and of the lateral deviations in congenital torticollis and the class of case exampled by the patients exhibited.—Dr. Alexander Stookes read a paper on Puerperal Eclampsia, with Especial Reference to the Causation and Treatment. He mentioned various statistics with regard to its occurrence, and considered the theories of its causation, whether due to intestinal absorption or renal diseases, or whether the cause was to be sought for in the ovum. He described several cases recently seen by him and discussed in detail the treatment that he advocated.—Dr. Arthur J. Wallace alluded to the use of veratrum viride, which reduced the pulse-rate down to 60 per minute. It had been shown that when the pulse-rate was low the fits rarely occurred. He recommended the veratrone of Parke, Davis, and Co. for this purpose.—Dr. H. Leith Murray said that as a result of some recent observations of his he was unable to find any placental cause for the condition.—Dr. O. T. Williams read a paper on Cod-liver Oil. He recalled the work that he and others had done on the influence of the oil upon the tubercle bacillus and upon the nitrogen metabolism and fat retention in phthisis. In diabetes phthisis was frequent, and this disease showed a diminution in the amount of unsaturated fats in the blood. In the first 50 years of the last century great advances were made in the treatment of phthisis, but the last 50 years did not show a proportional advance. All the authors of 50 years ago spoke very highly of the effects of the oil, but now it was rarely mentioned. Clinical and scientific reasons were presented for its greater use. The analyses of five oils were shown. The oil contained a very highly reactive unsaturated acid, having 18 carbon atoms and four double bonds. The fatty acids from the oil easily polymerised. The effects of oxidation were shown. The best oil was the least oxidised and contained by far the most unsaturated acids. It was prepared in an atmosphere of carbon dioxide and was nearly hydroxyl free. The oil acted in virtue of the peculiar unsaturated acid contained in it and not through the small quantities of the so-called active principles.—Several members then discussed some of the aspects of the treatment of phthisis.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Nov. 2nd, Mr. Stanmore Bishop, the President, being in the chair.—Dr. G. E. Loveday gave a communication on the Indian Ink Method of Demonstrating the Spirochætæ. The chancre, which should have had no treatment for two or three days previously, was washed and dried; the edge was abraded with a sterile instrument; and serum was squeezed out and a drop mixed with water and Indian ink in equal proportions. The mixture was spread in films on a slide, allowed to dry, and examined directly under the oil-immersion lens. The spirochæta pallida appeared white on a brown ground. Cells present showed up and served to indicate the size of the spirochætæ. Other methods were staining, which was unsatisfactory, and the dark-ground illumination method. This required a special condenser and some experience, but had the advantage of showing the characteristic movements of the spirochætæ. The simplicity and reliability of the Indian-ink method recommended it. Secretion from a primary sore hardly ever failed to show the spirochætæ. Spirochæta pallida must be distinguished from other spirochætæ, especially spirochæta refringens. The latter was, however, rare in the secretion from non-ulcerated chancres, and it was thicker and had fewer turns to its corkscrew than the spirochæta pallida. Since the Wassermann reaction was negative in 40 per cent. of cases of syphilis at all periods of the primary stage, the search for the spirochætæ in doubtful cases was valuable. Spirochæta pallida was found in mucous plaques, almost always in untreated chancres, usually in the papular syphilide, and only occasionally in juice and scrapings from glands and very seldom in macular or roseolar rash. Specimens of spirochætæ were shown by this Indian-ink method.—Mr. J. Arnold Jones communicated Some Points in the Diagnosis and Treatment of Acute Suppuration in the Frontal and Maxillary Sinuses. After a brief reference to the anatomy of the parts and to the etiology, the symptoms and differential diagnosis were discussed. It was pointed out that in these cases periodic attacks of neuralgia (mainly affecting supra- and infra-orbital nerves), as accurate and regular in their periodicity as in malaria, might occur. The main lines of treatment in antrum cases were: (*a*) washing out the sinus and puncturing the nasal wall in the inferior meatus with a straight hollow needle; and (*b*) endeavouring to establish drainage through natural ostia by applications of cocaine and adrenalin, followed up by menthol inhalations. In frontal sinus cases the same measures were resorted to for the establishment of drainage, which if ineffectual in 12 or 24 hours should be followed by amputation of the anterior end of the middle turbinal. Extra-nasal operation was rarely necessary in acute cases. Illustrative cases from Mr. Jones's practice were quoted.—Mr. J. Walters read a paper on the Practice of Psycho-therapeutics. After a brief historical retrospect, the various methods of inducing hypnosis were explained and special stress was laid upon the methods of Bramwell and Sidis. A description of Mr. Walters's own method followed. He had employed this method in about 200 cases and had come to the conclusion that a state of distraction or very light hypnosis was the best. The chief factor of this state undoubtedly was "pre-adjustment," the patient being placed in the most suitable condition to receive and to maintain the suggestions given. This was aided by reinforcement (or inhibition), repetition, and the restfulness of the state itself. Cases were cited proving the efficacy of the method in somnambulism, alcoholism, neurasthenia, the obsessions, and insomnia.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 4th, Dr P. S. Abraham, the President, being in the chair.—Before the work of the evening commenced the Keetley memorial medal, founded by the society for presentation to each president at the termination of his year of office, in memory of the late Mr. C. B. Keetley, founder of the society, was presented to Colonel T. Holbein Hendley, C.I.E., I.M.S., ex-president.—Dr. F. S. Palmer showed a case of Progressive Muscular Dystrophy, pseudo-hypertrophic type, in a boy aged 6 years. By careful inquiry no history could be obtained of nervous or mental disease in the family or its collateral branches. He had whooping-cough when four years of age, and since then had developed the typical features of his disease.—Dr. Palmer also showed a case of Myasthenia Gravis in a man, aged 41 years, with distinct wasting of facial muscles, particularly orbicularis palpebrarum, masseters, and buccinators.—Dr. T. Grainger Stewart remarked on the unusual mode of onset and the great wasting of the facial muscles. Replying to the President, Dr. Palmer said he believed that no constant pathological changes had yet been discovered in the central nervous system.—Dr. E. Arthur Saunders showed a case of Diabetes in a boy aged 5 years. No family history of glycosuria was obtainable. He had passed over 2000 grains of sugar in a day. Under dietetic treatment all sugar disappeared from the urine.—Dr. Henry Barnes mentioned the occurrence of diabetes in twins.—Dr. Reginald Morton showed skiagrams of a case of Congenital Syphilitic Disease of the Elbow-joint. In one, taken before treatment, no bony outline could be detected at the site of the joint; in the second skiagram, taken after four months' treatment, the bony outlines of the joint were clearly defined.—Dr. N. Bishop Harman showed a case of early Conical Cornea in a woman

aged 28 years. Evidence in this case showed that the condition had remained stationary for several years under treatment.—Dr. Bishop Harman also showed a case of Chronic Glaucoma relieved by Double Sclerotomy occurring in a woman aged 64 years. He showed also an instrument made for him by Messrs. Weiss for this operation.—Dr. S. D. Clippingdale showed a case of Conical Cornea.—Dr. T. Grainer Stewart showed a case of Exophthalmic Goitre and Syringomyelia in a female, aged 20 years, a typist, the chief point of interest being the involvement of the seventh cervical segment on the left side and its escape on the right, seen on both sensory and motor sides.—The President remarked upon the close resemblance of some cases of anæsthetic leprosy to syringomyelia; in one case of the supposed latter disease the bacillus of leprosy had been found.—Dr. Harold Pritchard showed a case of Transposition of Viscera with Congenital Heart Disease in a child aged 12 months.—Dr. Saunders said, as to the prognosis in congenital heart disease, this was more favourable in the pale than in the blue cases.—Dr. Seymour Taylor suggested that bismuth should be given so as to reveal by X rays if the stomach was transposed, and an enema of bismuth might reveal by the same means whether the sigmoid flexure and descending colon were on the right side of the abdomen.—Mr. W. McAdam Eccles and Mr. Frank Savery joined in the discussion.—The President showed: (1) Two cases of Multiple Keratosis in children. Solid CO_2 had been successfully used in these cases. He alluded to some cases in which there was some evidence of heredity. (2) A young woman with extensive Erythematous Lupus. (3) A case of X Ray Dermatitis in a young girl who had been treated for ringworm.

MANCHESTER PATHOLOGICAL SOCIETY.—A meeting of this society was held on Nov. 9th, Mr. Alex. Wilson, the President, being in the chair.—Dr. W. Mair read a paper on Enlarged Thymus and Sudden Death, and described seven cases of lymphatism in which he had made post-mortem examinations.—Dr. A. Hill Griffith described three cases of Tumour of the Optic Nerve which on microscopical examination proved to be respectively an endothelioma, a sarcoma, and a lymphangeioma.—Dr. J. Arnold Jones described a case of Antro-nasal Polypus.

Reviews and Notices of Books.

The Practice of Midwifery. Being the seventh edition of Dr. Galabin's "Manual of Midwifery," greatly enlarged and extended by ALFRED LEWIS GALABIN, M.A., M.D. Cantab., F.R.C.P. Lond., and GEORGE F. BLACKER, M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng. Illustrated with 503 engravings, many of the new illustrations specially drawn by T. W. P. LAWRENCE, M.B. Lond., F.R.C.S. Eng. London: J. and A. Churchill. 1910. Royal 8vo, pp. xxxi.–1123. Price 18*s.* net.

DURING the last 23 years Galabin's "Practice of Midwifery" has passed through six editions, and this in itself is a testimony to the value in which it is held by medical practitioners. The seventh and latest edition has been much enlarged, so that whereas in 1886 the Manual consisted of some 800 pages, this number is now increased by 40 per cent., whilst the size of the page is a good deal larger. The present edition has been thoroughly revised and to a large extent rewritten. In this undertaking Dr. Galabin has had the able assistance of Dr. G. F. Blacker and the work has been very thoroughly done, in fact "The Practice of Midwifery" is, in our view, the best text-book on the subject yet published by British authors.

The subjects that have been chiefly revised are the development of the ovary and of the early ovum, the physiology of the fœtus and of the puerperal state, the mechanism of labour, the lower uterine segment, the pathology of eclampsia, hydatidiform mole, accidental complications of pregnancy, narcosis in labour, vaginal and extra-peritoneal Cæsarean section, and pubiotomy. A new chapter has been added on injuries and diseases of the fœtus. All this has entailed an addition of some 200 pages to the sixth edition. The treatment of "accidental hæmorrhage" is perhaps the least satisfactory part in the book since it is difficult to discover what the real opinion of the authors is on this subject. In former editions Dr. Galabin condemned the treatment of plugging the vagina. In this edition the authors state that "experience appears to justify this treatment, which is now generally accepted," but find that "the statistics of the results of treatment by plugging are very slightly better than those of the old method," this slight gain being due to the improvements in antiseptic midwifery, while they ask us to remember "that the treatment is a dangerous one in unskilful hands if either the plugging is not effective or antisepsis not fully maintained," and "that it is only available when the membranes are unruptured." From a perusal of all this it seems to us that the student might well be excused if his answers at the examination failed to satisfy the examiner.

The book is beautifully printed on excellent paper and the new illustrations by Mr. T. W. P. Lawrence are very good, and in these respects the seventh edition is far in advance of any that preceded it. In other ways than those which have been mentioned the manual has been brought well up to date and an examination of any section will show that the revision has been complete, while from the title page it would appear that Dr. Blacker is to be regarded as joint author. It would be as well, therefore, in future editions to eliminate the personal pronoun which is found to be so freely scattered in this edition. We presume that "I" when used refers to Dr. Galabin, but this is only presumption, and it may be that sometimes it refers to Dr. Blacker.

The authors and publishers may be congratulated on the production of such a handsome and complete treatise on the science and art of midwifery.

Diagnostic Methods, Chemical, Bacteriological, and Microscopical. A Text-book for Students and Practitioners. By RALPH W. WEBSTER, M.D., Ph.D., Assistant Professor of Pharmacological Therapeutics and Instructor in Medicine in Rush Medical College, University of Chicago, &c. London: Rebman, Limited. 1909. Pp. 641. Price 26*s.* net.

MANY as are the occasions in medical practice in which help has to be sought from the clinical laboratory, yet the full debt owed to this institution is scarcely realised until the appearance of some such volume as that now before us, which collects together the multitude of procedures at present available for the investigation of disease. The first chapter is devoted to examination of sputum, and the characters of the secretion, macroscopic and microscopic, and the objects to be looked for in it are first described, and then special consideration is given to the sputum seen in different diseases respectively. Chapter II. deals with oral, nasal, aural, and conjunctival secretions; and we note that the recently described "Prowazek-Greeff bodies" in trachoma are described and depicted. Examination of the gastric contents occupies Chapter III.; the various tests used are described very fully, the conditions found in different gastric disorders being separately considered. In Chapter IV. the fæces are dealt with, and this leads by a natural transition to a discussion of parasites in Chapter V. Nearly 200 pages are devoted to the examination of the urine in Chapter VI. We note the author's preference for a means of estimating sugar, known as Purdy's method, in which glycerine takes the place of ammonia in the copper test solution; also his belief that Russo's test (methylene blue) is of value in the diagnosis between enteric fever and general tuberculosis. A short chapter is devoted to the secretions of the genital organs, and then a long chapter of over 200 pages is given to the examination of

the blood. Some useful illustrations are given of the curious ring-shaped and other bodies sometimes seen in the red corpuscles, which may easily give rise to mistakes. The last two chapters deal with transudates and exudates, and with the secretion of the mammary glands.

The book appears most complete and exhaustive. It is copiously illustrated, many of the pictures being in colours and the majority well reproduced. It could hardly be expected that all the many sides of the subjects treated of would be equally well done, and we think the chemical part of the book is perhaps stronger than the rest. But the standard of the sections on physical and microscopical examination is by no means a low one, and we congratulate the author on the care with which he has compiled his information and the skill with which he has arranged it. A certain amount of matter is included which is hardly a part of diagnostic method, such as the etiology of certain conditions, the dosage of vaccines, and a short account of Ehrlich's theory of immunity. There are a good many printer's errors scattered about, such as "oligema," "anerobic," "trichiurs," "distomum couns" (canis?); and mistakes such as "spirochaete pallidae," "this extracted feces." The writing is also careless in places, as in the sentence: "This test has very much the same relation to the detection of sugar in the urine as does Heller's nitric acid test towards albumin in the urine." There is an adequate index.

LIBRARY TABLE.

The Pathology of the Living and other Essays. By B. G. A. MOYNIHAN, M.S. Lond., F.R.C.S. Eng. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 260. Price 10*s.* net.—This is a reprint of a number of essays which have appeared during the last few years in various medical periodicals, and many of them are certainly deserving of republication. The title essay treats of the question of the pathology of the abdomen disclosed at operations, as contrasted with the pathology found at the necropsy, and many useful hints are given as to the misunderstanding of abdominal symptoms which may occur from a want of appreciation of the true explanation. Several of the other papers are of almost equal interest, and we would mention specially the article on the "mimicry of malignant disease of the large intestine," for there is little doubt that many cases in which a mass is felt in the colon are of chronic inflammatory origin and are not malignant.

Les Formes Larvées du Paludisme: Diagnostic et Traitement. By Dr. BASILE MOUSSÉOS. With 18 illustrations. Paris: Vigot Frères. 1910. Pp. 144. Price Fr.3.50.—Dr. Mousséos has had a long experience of malaria during his 20 years' residence in a malarious district in Asia Minor. He adopts the classification of the disease into (1) intermittent fever, (2) "fièvre larvée," and (3) malarial cachexia. He compares paludism to a tree, of which intermittent fever is the root, *fièvre larvée* the trunk, and the malarial cachexia the branches and fruit. The term "*les fièvres larvées*" is used generally by French writers to denote "different affections of a periodic character, having a course more or less obscure, presenting some analogy with intermittent fever, and yielding to similar treatment." The book comprises six chapters, in the first of which the plasmodium in its various forms is described as also the author's method of examining the blood of a malarial patient. In the next he gives a description of *fièvre larvée*, with illustrative cases, and discusses how it may be diagnosed. The third chapter is a consideration of the value of quinine in combating the plasmodium in *fièvre larvée*. The "plasmodic toxæmia" forms the subject of the fourth chapter, and this is followed by one on hæmoglobinuria. In the last chapter the author gives his general conclusions. Referring to his modes of treatment, he says that the only objection is the large number of injections necessary in treating a case of malignant fever or a malarial cachexia. But to meet this he has had prepared at the laboratory of the "Pharmacie Centrale de France" a product which contains all his medicaments "difficilement synthétisés." The work is dedicated to Professor Laveran, and Dr. Alexandre Cawadias contributes a preface. The book is interesting, being written in a style which at once secures the reader's attention.

A Natural Method of Physical Training. By EDWIN CHECKLEY. London: T. Werner Laurie. 1910. Pp. 174. Price 1*s.* net.—The author believes that there is more "straining" than "training" in a good many popular systems of physical development. The method he advocates does not require any apparatus, and "will build up the frame of the slender and reduce the unwelcome proportions of the corpulent without the employment of machinery or harsh and weakening methods of dieting." The main point in Mr. Checkley's view appears to be the learning to breathe properly; "to learn to breathe is to learn the A B C of physical health." Various exercises are described for developing the muscles and joints, and advice is given as to the general carriage of the body. The author's views are mainly rational and the exercises described are likely to improve the muscular development, the respiratory capacity, and the general health. In reference to the physical training of girls, "ludicrously guarded against exercise that they need as greatly as boys," his arguments do not apply to the conditions of female education that obtain at present, although they would have been to the point 20 years ago. The last chapter of "Hints and Suggestions" contains good advice, and except for the peculiar views the author entertains as to the mechanism of respiration and the curvature of the spinal column, the suggestions in the book are sensible and practical. The work is written in a loose style and the spelling is the author's own, where it does not follow American usage.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—In the current number of this journal Professor David MacEwan discusses Bier's treatment by venous hyperæmia, which he finds useful in open tuberculosis and in acute circumscribed inflammations, such as carbuncles, abscesses, and bursitis. Professor James D. Heard writes on the significance of transient cerebral crises and seizures as occurring in arterio-sclerosis, and quotes the various views that have been held as to their pathology; and Dr. W. E. Foggie records a case of congenital dextrocardia, with "cor triloculare biventriculare." Dr. J. D. Comrie and Mr. J. S. Fraser report the results of their experience in the examination of the sphenoidal sinuses in 50 cases, and note the need for microscopical as well as naked-eye examination to determine the actual existence of inflammatory changes. Dr. H. Ruthven Lawrence points out the advantages of scopolamine-morphine as an anæsthetic in maternity practice.

The Medical Chronicle.—In the October issue is published the first part of a valuable thesis by Dr. Robert Lakin on the Blood and Urine in Cardiac and Renal Dropsy. He concludes that cardiac dropsy is purely mechanical, there being no plethora or hydræmia; whereas in renal disease there is hydræmia, which is not, however, the cause of the œdema. He comes to no definite conclusion as to the relationship between retention of chlorides and œdema. Dr. R. T. Williamson gives an account of the proceedings at the Third International Congress on School Hygiene, held in Paris, 1910; and Dr. Robert E. Lord records a case of perforation of a typhoid ulcer in a boy, aged 11 years, with recovery after operation.

The Birmingham Medical Review.—In the September issue of this review Dr. J. Douglas Stanley writes on Phthisis and the Municipal Sanatorium, emphasising the importance of after-care of patients whose disease is apparently arrested. Dr. James E. H. Sawyer discusses bruits heard over the manubrium sterni in children, and concludes that they are formed in the jugular veins and conducted in the direction of the blood-stream, and that they are of no pathological significance.

The West London Medical Journal.—Perhaps the most interesting paper in the October number of this magazine is that by Dr. A. Elliot, in which he records two cases of acute hæmorrhagic pancreatitis. In one case no gall-stones were present, and in the other only a single large stone in the gall-bladder, which could hardly have been the cause of the trouble. Dr. J. A. Coutts comments on pyloric stenosis in infants and narrates two cases, both of which ended fatally, one after and the other without operation. Mr. N. Bishop Harman summarises his experience of the Wassermann reaction as an aid to diagnosis in ophthalmic work and expresses a favourable opinion as to its value; and Dr. Phineass S. Abraham discourses pleasantly on specialists and specialisms.

Jahrbuch für Kinderheilkunde. September, 1910.—In this number Dr. Martin Thiernich writes on the subject of suppurative diseases of the kidneys and urinary passages during infancy; his article is illustrated with clinical cases. Dr. Eva Hoffmann contributes an article on fat absorption in infants and methods of estimating the pancreatic ferments in the fæces. She concludes that the diastatic ferment is better than the tryptic as a criterion or index of pancreatic efficiency. Dr. Franz Topovski gives interesting details of a case of maldeveloped intestine in an infant simulating congenital hypertrophic pyloric stenosis. The cæcum and appendix were dislocated in an aberrant position over the stomach in such a way that they exercised pressure on the pyloric end of the stomach and induced an intractable condition of vomiting.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

ARCHENA WATER.

AMONGST the health resorts and watering-places in Spain which deserve a wider patronage than they have hitherto received is Archena, which is situated in a beautiful valley on the right bank of the Segura river. The waters are thermal and consist of a solution chiefly of the alkaline salts of soda, including sodium sulphate, sodium carbonate, with carbonates and sulphates also of lime. The gas dissolved in the water contains sulphuretted hydrogen. We have made an analysis of the water, and in spite of the time which had elapsed since the sample was taken at the source we found sulphuretted hydrogen present. Further analysis showed that the water was only slightly mineralised, the total salts amounting to 3·74 grammes per litre, including the salts mentioned above. There were traces of other salts present, including iodides. We learn from Dr. W. H. Russell Forsbrook that the establishment at Archena contains a complete installation of baths, and includes swimming baths, shower and dry vapour baths, spray applications, inhalations, and other hydro prescriptions. There are excellent social attractions provided also. The water issues at a temperature of 132° F. and is used both for external application and for drinking purposes. Dr. Forsbrook reports that very satisfactory results are obtained from the use of the waters in muscular rheumatism and gout, neuritis, neuralgia, sciatica, lumbago, neurasthenic joint trouble, and in the stiffness of joints arising from old injuries, and especially in osteo-arthritis, in cutaneous skin diseases, and in chronic catarrh of the mucous membranes. The sanitation and the dryness and temperature at all seasons have received favourable observations. Archena is reached from Paris *viâ* Perpignan, Barcelona, and Valencia, and is about 59 hours' journey from London.

CERTIFIED COMPLEXION SOAP.

(ARMOUR AND CO., LIMITED, ATLANTIC HOUSE, HOLBORN VIADUCT, LONDON, E.C.)

The addition to soap of hamamelis virginica seems to us to be a suggestion of some value, inasmuch as witch hazel has a distinct reputation as an elegant astringent and hæmostatic. The soap, of course, is cleansing and the hamamelis serves as a healing application to a broken skin. The extract has thus been used for chapped hands, chilblains, and for skin roughened by exposure to weather. Complexion soap we found was a good firm white opaque tablet, delicately scented and economical in use. It is highly milled and practically free from moisture. There was no evidence of free alkali present. The soap is soothing and pleasant to use, and we have formed a good opinion of it.

MEDICATED THROAT PASTILLES.

ALLEN AND HANBURYS, LIMITED, 37, LOMBARD-STREET, LONDON, E.C.)

Two pastilles submitted to us are the basis of two excellent formulæ for application in affections of the throat. The pastilles are transparent and dissolve slowly, ensuring a prolonged application of the medicaments, which are admittedly useful in certain irritable conditions. The first formula includes formaldehyde and menthol, which form a stimulating, antiseptic, and expectorant combination of use in hoarseness and sore-throat. The second pastille contains formaldehyde and cinnamon oil, which is an excellent formula for use in affections of the mouth, nose, and throat due to specific organisms. The demulcent effect of the basis in each case is a decided advantage.

RUSTIC ALE.

(BRANDON'S PUTNEY BREWERY COMPANY, LIMITED, TWICKENHAM, MIDDLESEX.)

This is a beer of small alcoholic value, on account of which it can almost be regarded as a temperance beverage, the alcohol found not exceeding 2·83 per cent. by weight or 3·55 per cent. by volume. The beer belongs to the class of light malt liquors of low gravity, the specific gravity of the dealcoholised beer being only 1017. The malt extractives, therefore, are, as we found, moderate in amount—namely, 4·46 per cent. The mineral matter amounted to 0·16 per cent. and the malt sugar to 2·28 per cent. We believe it to be a correct statement that this beer is brewed from malt and hops only, and in spite of its agreeable light character we could not trace the presence of any objectionable preservative.

CALMINE POWDER AND TABLETS.

(THE CROWN CHEMICAL WORKS, LIMITED, MARSH GATE LANE, STRATFORD, E.)

Calmine is a pure white powder which is soluble in water, and contains diethylbarbituric acid combined with sodium. It possesses certain advantages over the acid itself, which is commonly known as veronal or diethylmalonyl urea. It has a decided soporific action, and has been employed in cases calling for the relief of pain and in nervous affections generally, especially of the acute type. It has been used in epilepsy, hysteria, and mania, but should not be employed save under medical advice.

TONI-KOLA.

(AGENTS: THE VICTORIA WINE COMPANY, 12 TO 20, OSBORN-STREET, LONDON, E.C.)

The value of kola extract in fatigue and exhaustion is well known, and an excellent vehicle for its administration

—of course, under medical direction—is a sound wine. Our examination of toni-kola enabled us to confirm the presence of caffeine. The alcoholic strength of the wine is not excessive—not much more than that of claret; it amounted to 11·77 per cent. by weight. The total extractive matters amounted to 15·71 per cent., and consisted chiefly of grape sugar. Toni-kola is prepared in France, and is an example of the pharmaceutical skill commonly exhibited by the pharmacists of that country.

New Inventions.

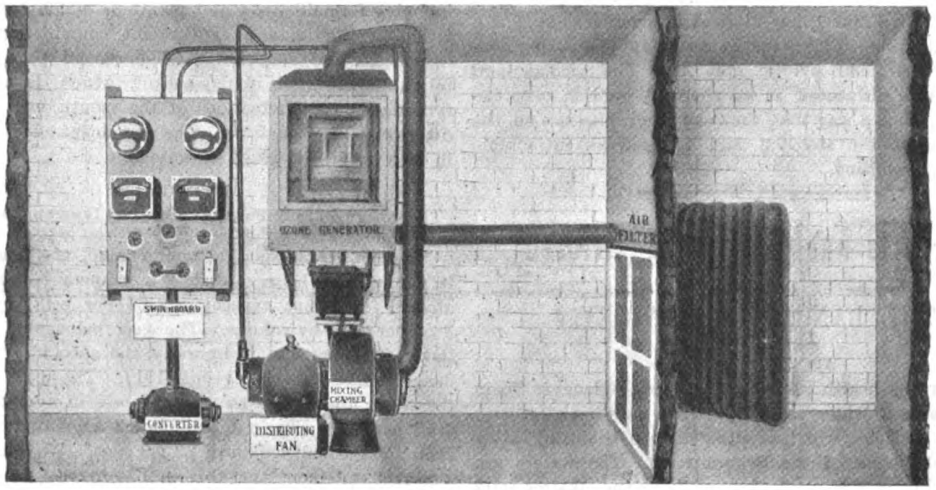
OZONE GENERATORS.

OZONE is a common constituent of pure unsullied air and owing to its powerful oxidising power its presence may be taken as indicating the absence of easily oxidised organic impurities. The pure air of the open country, the seaside, or of high altitudes which is prescribed for its vitalising influences invariably contains ozone which is, many believe, directly connected with the restorative powers of the pure atmosphere.

One thing, at any rate, is certain, and that is that the presence of ozone connotes pure air. This fact has led to the idea of applying ozone to the purification of air and to systems of ventilation. The suggestion obviously involves the use of efficient apparatus for the commercial production of ozone. The production of ozone by electrical discharge in the presence of air has long been known, but it has taken some time to bring forward an installation which could be trusted to discharge a stream of ozonised air free from oxidised nitrogen bodies. Nitrogen oxides, as well as ozone, are readily enough obtained when air is exposed to the influences of electrical discharge, but a careful study of the conditions under which these oxides are produced has enabled a differentiation to be made so that ozone can be produced to the exclusion of these impurities. This was the starting-point of the ozone generators of Ozonair, Limited, of 96, Victoria-street, Westminster, London, S.W., who now manufacture for a very large number of applications ozone generators which give ozonised air absolutely free from nitrogen acids. The generator applied to a system of ventilation and supply of pure air is demonstrated in the accompanying illustration. On the right in the illustration is the inlet chamber for the fresh air, which can be either cooled or heated in this chamber. The air is next drawn through the filter, which frees it of all suspended matter, smuts, and so forth, and at the same time absorbs such soluble gases as ammonia and sulphurous acid, which are commonly present in the air of large towns. The position of the distributing fan, switchboard, and ozone plant are obvious in the illustration, and the whole plant is operated by two regulating switches on the switchboard. The amount of air passing and the proportion of ozone within certain limits can be regulated at will. The air so obtained imparts a delightful refreshing sensation, is cool, and is most comfortable in respiration. The apparatus with due precautions relieves the air of all oppression and stuffiness, and hence the appreciation of it in crowded places, churches, public halls, theatres, clubs, workshops, steamships, and so forth. Modifications of the apparatus are made to meet the requirements of variable atmospheric or climatic conditions in order to ensure, in spite of variations of pressure, temperature, and degree of moisture, the steady production of an air ozonised to a definite point.

The Ozonair system has been adapted to the sterilising of water. To be effectual this method must provide for an intimate contact of the ozone with the water, and so the water is first distributed in the form of fine spray which impinges upon the upper part of a pile of glass spheres, through the interstices of which the stream of ozone is caused to ascend whilst the liquid, already partially ozonised and sterilised, descends over the surfaces of the spheres in a very fine film. Finally, after leaving the ozonising pile, the water is discharged in fine jets through ozone. The apparatus effecting all this intimate contact of the water with ozone is most ingeniously designed, and it is not surprising to find that the ultimate effluent is sterile, free from organic impurities, and blue like a mountain stream.

Ozone apparatus has also been designed for the bleaching of various articles, and considerable success is attending these experiments, even on the commercial scale, while experiments also give promise of ozonised air being successfully used in the preservation of meat. Experimental plant for laboratory and medical and surgical purposes are being manufactured, and here there is an interesting field for investigation which is very materially helped by the fact that by merely switching on the electric current an unlimited ozonised air-supply may be obtained for the purpose. The types of ozone generators, in short, are as numerous as their possible applications.



EASTBOURNE AND ITS CORONER.—The town of Eastbourne becomes a county borough on and from April 1st next. The whole question of the adjustment of the financial relations between the county of East Sussex and Eastbourne has been considered by a specially appointed committee which has recommended, among other matters, that until the death, resignation, or removal from office of Mr. George Vere Benson, and until a coroner is appointed for the borough, Eastbourne shall continue to be within the district of the county coroner as if the same had remained in the county of East Sussex. The county council at its meeting on Nov. 8th ratified the recommendation.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 19, 1910.

The Suffolk Epizoötic of Rat Plague.

THE fact that it is now nearly two months since any suspicious cases of human plague occurred in East Suffolk should in material degree reassure the public that the chances of man being attacked are small, more particularly so when regard is had to the inhibiting effect of the approaching winter. An active crusade against rats has been in operation for some time past, and has resulted in the weekly destruction of thousands of these vermin and their attendant fleas, any of which may have been carriers of plague bacilli, and outside the dwelling the risk of infection through the flea in this country is not one to give rise to much anxiety. As yet we are not apparently quite clear as to the extent of the invaded areas, but Local Government Board inspectors are, we know, visiting districts in Suffolk and Essex with a view of determining this important point. This is obviously the right line to pursue, but the negative side of the inquiry presents difficulties, as it will be hard to establish the absence of rat infection in any given district. For the most part the local landowners and tenants appear to be loyally coöperating with the authorities in the work of destruction, which naturally appeals to the farmers from an economical side altogether apart from its health aspects. If there are any backward or recalcitrant occupiers, and we have no doubt that there are many, they have been handed over to the authorities by the prompt issue by Mr. BURNS of the regulations relative to rat destruction, which would appear to confer upon the district councils ample power to enforce rat destruction throughout the whole of their areas. Doubtless the total extermination of rats is a difficult—some would say impossible—task, and we are not aware of any instance in which extermination has been accomplished over a wide area, whether in this or any other country. As vacancies are produced by wholesale death-dealing in one district so are they rapidly filled up by the invading hordes from adjoining areas, and equally the results of action in one area lead to dispersion of large numbers of rats into neighbouring districts. But this is no argument against a wholesale crusade against rats with the object of reducing these animals to their smallest proportions, and thereby diminishing as far as possible the chances of human infection.

Next to a war upon rats comes the important question of domestic cleanliness, which means freedom from insects. The history of plague shows that it invades the overcrowded houses of the unclean, in whose dwellings there are likely to be both rats and their fleas, so that all general sanitary precautions fight against the chances of infection. As is insisted upon in the recently issued memorandum of the principal medical officer of the Local Government Board, there are other steps to be taken by communities and health authorities besides the destruction of rats and their parasites. The experience of Glasgow shows that in this country plague in man can be easily controlled under conditions of efficient sanitary administration, and of this fact there can be little doubt. Things are not what they were 250 years ago, when what was known as the Plague of London occurred, since which time England has set an example to the whole civilised world in the matter of epidemiology and sanitary administration, and the country has been mapped out into sanitary areas each with its medical officer of health and sanitary inspector, while, more recently, county councils, with ever-increasing public health functions, have come into being. And in the matter of human plague, should there possibly be cases, the position is much what it would be were typhus or enteric fever or small-pox in question, and the key to control is embodied in the following points: (*a*) the prompt notification of all doubtfu cases either of the bubonic or pneumonic type and the treatment of such suspicious cases administratively as plague until the reverse is demonstrated; (*b*) isolation accommodation for the patients and the observation of all contacts; and (*c*) facilities for preventive inoculation, and a supply of trained nurses to deal with cases of pneumonic plague. As the official memorandum observes, bubonic plague is the rule and pneumonic plague the exception, but it is the little nests of the latter variety which create proper alarm in invaded localities. Professor W. J. SIMPSON'S letter in our columns this week emphasises the fact that Europeans enjoy no immunity from plague, and the public feeling now surely is that into our campaign against rat plague, and our provision for such human cases as may possibly occur, no question of economy should enter. The damage done to agriculture in certain of the invaded districts by the refusal of customers to accept local produce must already have been enormous. There is, in our view, no justification for alarm in this sense, as the danger of the contraction of plague by ingestion is very small. This all the work by the Madras Plague Commission shows. But public confidence has to be restored, and if this necessitates the voting of money by Parliament to aid the local authorities in their efforts it would be well and economically expended. The primary duty of dealing with the situation no doubt devolves upon the local authorities, who should be urged by all available means to maintain the campaign which they have begun.

In many districts in rural areas here may be found part-time medical officers of health and unqualified sanitary inspectors, and in these cases their efforts ought to be supplemented by the temporary appointment of experienced officers. Special knowledge of plague is in no sense essential, since if all suspicious cases are forthwith isolated, and bacteriological investigation made, knowledge of ordinary infectious diseases should ensure the adoption of adequate precautions. No doubt the local authorities will be advised by the trained epidemiologists and administrators of the Local Government Board, and, with the aid of the county council local administrators,

they should prove equal to the occasion, the action of the Local Government Board in providing bacteriological testing being particularly useful. Considerable speculation has arisen as to the length of time during which this rat plague has been in existence in East Suffolk and as to whether anything approaching a similar state of affairs exists elsewhere unrecognised. No answer can as yet be furnished to these questions, but it should be borne in mind that the black rat (Mus rattus), which is the bearer of plague to this country, is apt to be introduced into this country through any shipping which bears cargoes, and especially cargoes of grain, from any of the plague-infected ports in South America, Russia, or elsewhere, a reflection which at once leads us to ask what is the distribution of rat plague in these countries and what steps are taken to ascertain whether rats from them are plague-infected or not. What we should much like to know is whether the rats in localities where there has recently been human plague have been demonstrated to be free from this disease. An investigation of this nature would reveal to us what is the real risk of the importation of plague rats into this country in face of the recognised difficulties of ensuring the destruction of rats on board ship or of preventing their access to the shore. Most of the resources for preventing the egress of rats from ships are less efficacious than was formerly believed, and the examination of the rats in certain of our ports has shown that by some means or other the black rat has found his way ashore. The consequent possibilities must be remembered.

Housing Regulations and Back-to-Back Dwellings.

THE regulations governing the inspection of districts under the Housing and Town Planning Act of 1909, now issued by the Local Government Board, contain several requirements which are of importance to medical officers of health and others whose duties bring them into relation with insanitary dwellings and unhealthy slum areas. The regulations aim at extending the practice of systematic sanitary inspection of dwellings, which has hitherto been followed by the more progressive of our local authorities, to all sanitary districts in the country. All urban and rural district councils are now required to arrange for the necessary inspections of dwellings to be made by or under the direction of the medical officer of health, who is periodically to submit lists of dwelling houses and areas in the district, early inspection of which is in his view desirable. The inspection is to be of a comprehensive character, and in addition to the determination of a series of questions specified in the regulations, is to include examination for any defects which "may tend to render the dwelling house dangerous or injurious to the health of an inhabitant." The Act of 1909 has placed local authorities in a better position to deal with questions affecting insanitary property by the issue of closing orders, the preparation of improvement schemes and like measures; and the regulations now require that these bodies should deal with reports as received from the medical officer of health, and record the directions which they give and the results of their action, reports on these matters being also transmitted to the Local Government Board. A considerable addition has thus been made to the responsibilities and work of district medical officers of health. The regulations should increase the authority of the medical officer when reporting upon insanitary houses and advising what should be done with them, though their issue will be held by many further to emphasise the importance of security being given to all medical officers of health in their tenure of office.

The Housing and Town Planning Act contains a clause, which gave rise to considerable controversy in Parliament forbidding the future erection of back-to-back houses as dwellings for the working-classes, and limiting the erection of tenement houses in which the tenements are placed back-to-back to buildings which the medical officer of health certifies to have sufficient available ventilation. The first of these provisions will effect an important change in the type of house built in several industrial towns in Yorkshire, where back-to-back dwellings, either in rows or in blocks of four houses together, have been erected in large numbers under the provisions of local Acts and by-laws. These houses have an undeniable advantage in the cheapness with which they can be built and let; but for many years, especially since the well-known report by the late Dr. F. W. BARRY and Mr. GORDON SMITH in 1887, on back-to-back houses, the drawbacks of this type of dwelling, in a sanitary sense, have been generally recognised. Rows facing north get little or no sunshine into any part of the house, while those facing south, having all the rooms exposed to the sun, may become intolerably hot; the rooms are conspicuously stuffy, while much inconvenience and nuisance result from the absence of a backyard and the position of closets and ashbins. The probability that a higher death-rate exists in houses built back-to-back, when compared with "through" houses in the same neighbourhood, was indicated for the town of Salford by Dr. J. W. TATHAM for the years 1879–83, and by similar statistical comparisons which have since been made in a few localities, notably in Shipley by Mr. HERBERT JONES, in Bradford by Dr. W. A. EVANS, and in Manchester by Dr. J. NIVEN. An extensive inquiry into the subject has now been made for the Local Government Board by Dr. L. W. DARRA MAIR, whose report, with an introduction by the Board's medical officer, has lately been issued as a Parliamentary paper (Cd. 5314). In order to avoid, as far as practicable, the many sources of error which are liable to arise in the comparison of populations for this purpose, Dr. DARRA MAIR extended his investigations over 13 industrial towns in the West Riding of Yorkshire in which back-to-back houses are common, and limited the comparison to houses in good structural condition situated in relatively healthy areas. With the aid of the medical officers of health concerned, the vital statistics of these houses were obtained for a ten-year period, and by means of special inquiries in each district material was obtained for the correction of death-rates for the age and sex distribution of the populations. The inhabitants of the "through" and "back-to-back" houses compared in the report were of the same class, with similar occupations and wages, though the rent of the "through" houses, averaging 5*s*. 6*d*. a week, was naturally

higher than the rent of the "back-to-back" houses, which averaged 4*s.* 6*d.* a week. The corrected average annual death-rate from all causes was found to be greater in the back-to-back houses than in the "through" houses to the extent of 15 per cent. When only those back-to-back houses built in continuous rows were taken for comparison the excess was still greater, amounting to over 20 per cent. Back-to-back houses in blocks of four, each house having means of side ventilation, showed an average annual death-rate similar to that in "through" houses. The outstanding causes of deaths, which produced the excess of mortality in the back-to-back houses, were pneumonia, bronchitis, and other pulmonary diseases (exclusive of phthisis), and diseases of defective development and malnutrition in young children. An excess of mortality in back-to-back houses from infectious fevers and from phthisis could also be traced, but these increments were less conspicuous than in the case of deaths from the causes above mentioned.

The chief sufferers from residence in back-to-back houses, it would appear, are infants and young children and old persons. In part, this probably results from the greater liability of both young and old to death from pulmonary diseases other than phthisis. The higher mortality in infants was also in large degree due to an excess of deaths certified as due to atrophy, debility, marasmus, convulsions, and teething. From the first three of these causes the mortality in the back-to-back houses stood to that in "through" houses in the proportion of 169 to 100; from the last two the ratio was 164 to 100. These conditions are associated on the whole more closely than any other group of certified causes of death with the effects of impaired nutrition, imperfect growth, and abnormal development of the young child, and it is scarcely to be doubted that in the earliest period of life the nature of the home, especially, perhaps, its facilities for obtaining fresh air and sunlight, exert a powerful influence on their production. The value of these statistical observations is increased by the fact that the broad conclusions which are indicated by a study of the figures in the aggregate are also supported by the figures for the individual towns in which the investigations were made, in practically all of which an excess of mortality was found to have occurred in the dwellings of the back-to-back group. The information obtained by Dr. DARRA MAIR is obviously capable of a wider application than to back-to-back houses in Yorkshire. The construction of many blocks of flats and tenements may usefully be considered in the light of this report, which should be of material assistance to medical officers of health in advising upon the wholesomeness of existing working-class dwellings and the type of houses which should be supplied in future building schemes.

Undergraduates and Behaviour.

IT is probable that the uses of the safety-valve were first discovered by administrators rather than by mechanicians. Wherever human beings were assembled together under discipline, experience must have shown, before long, to any who were placed in positions of authority, that the reins of that authority might from time to time be judiciously relaxed, and that the temporary excesses consequent upon the relaxation were eminently conducive to the general maintenance of satisfactory conditions of control. The French Admiral who, in 1870, was called upon to proclaim to the fleet at Brest the establishment of the French Republic, with its watchwords, "*Liberté, Égalité, Fraternité*," is said to have concluded his address by a reminder that "*La Liberté n'embarque jamais*," and it is abundantly clear that the fulfilment of the conditions thus indicated would be enormously aided by the possession and exercise of the freedoms which Jack ashore has always permitted himself, and which, in all maritime nations, have usually been regarded with indulgence, if not with absolute satisfaction. The various holidays of mediæval societies were often little more than periods of salutary emancipation from customary restraint, and the licence of tongue of the mediæval jester was often but a vicarious departure from the reticence commonly enforced upon the people. From quite ancient times, when the undergraduates of our universities lived under a sternness of discipline which their modern successors would not tolerate for a day, the authorities who controlled them were well aware that there must be occasions on which this discipline should be relaxed; and so it came about that the times of the public conferring of degrees were recognised as occasions of this kind—as seasons of chartered libertinism, during the continuance of which the undergraduates obtained a freedom of speech not ordinarily permitted to them, and the dons were compelled to listen to opinions, not always of a complimentary character, but which, nevertheless, it might often be good for them to hear. And so, during Commemoration at Oxford, or the corresponding festival at Cambridge, it often befell that the serious portion of the proceedings received but scanty attention from the undergraduates among the audience, and that their noisy humours diverted attention from the eloquence of the public orator. These humours in time were carried to such a point that, some five-and-thirty years ago, it became necessary at one seat of learning to disperse the disturbing elements, to remove the undergraduates from the gallery formerly allotted to them, and to distribute them among the general audience who were every year attracted to the scene.

The more or less humorous outbreaks at the older universities had once, as we have shown, some justification in history; and were originally the only opportunities possessed by the undergraduates of protesting against unpopular persons or enactments. In modern times, or in modern seats of learning, the students are placed under wholly different conditions, and have but slight excuse for attempts to maintain or to imitate customs which have lost their original meaning, and which, transplanted into new and strange surroundings, may easily become mere vulgar survivals of barbarism. It is therefore with much regret that we have recorded, in recent issues of THE LANCET, the misbehaviour of undergraduates at Bristol, at Edinburgh, at Dublin, and at Cork. At Bristol they had provided themselves with wind instruments and banners, and their interruptions are described as making up in noise for their deficiencies in point of wit. At Edinburgh some of the finest passages of Mr. WYNDHAM'S address were drowned by noisy interruptions from the top gallery. At Dublin both the address of Sir CHRISTOPHER NIXON and the ceremony of conferring degrees were interrupted by the rowdyism of a certain number of students. The climax of disturbance was reached at Cork,

where the undergraduates, not content with verbal insults, pelted the auditorium with paper pellets, with sugar, and ultimately with pieces of stinking herring, one of which narrowly missed a lady who was advancing to receive her degree, and actually struck one of the professors. It is said that an old Irishwoman, whose speech betrayed her, was once asked in London whether she did not come from Cork, and that her prompt reply was: "An how did your honour guess that? Was it by my good manners?" Her claim would once, we believe, have been completely justified by the prevailing customs of the locality; but "good manners" must long have departed from a region where hobbledehoys can pelt ladies with stinking fish, and be regarded by other hobbledehoys with tranquillity, or even with approbation. It is something to learn from our correspondent that the Cork students guilty of these outrages were "comparatively few," but it is certain that these few would not have ventured to act as they did unless they had felt secure of at least the passive acquiescence of those around them. In a more satisfactory state of public opinion they would have been silenced by their neighbours, even if they had not been ducked.

We are glad to say that there is no trace of evidence to connect the perpetrators of these vulgarities with the medical faculty of any one of the universities concerned. Something like BOB SAWYER may once have had a real existence; but he is now as extinct as the megatherium. The last serious attempt to resuscitate him was made some time in the seventies of the past century, in an unfortunate article in the *Fortnightly Review*, which, a reply to it having been refused insertion by the offending magazine, was soon afterwards dealt with as it deserved in the *Contemporary Review*. Since that date the gravity of the work of the medical student has been thoroughly recognised by all responsible writers, and the public has come to understand that the course of medical study compels its pursuers to lead a sober and steadfast life. The medical student of to-day, and, indeed, of many days gone by, is "serious in a serious cause," and is too conscious of the nature of the duties for which he is preparing to allow himself to be identified in any marked way with rowdyism. But in whatever faculty they may chiefly occur, the outbreaks to which we have drawn attention are much to be regretted, and it is difficult to suppose that some responsibility for them does not attach to the authorities of the universities concerned. If this be not the case, if they are merely the ordinary consequences of insubordination and of ill-manners, they point at least to a responsibility lying farther back, to a remissness on the part of those who were concerned with the earlier training of the offenders, or to impediments arising from a state of national feeling, comparable to that which undoubtedly exists in lower strata of the community. Our public elementary schools are turning out, year after year, too many children who, having learnt nothing by which they can immediately profit, have no desire for knowledge and no consciousness of its value, and who respect little, because they have not had their attention duly called to the things which are worthy of respect. If similar conditions are to affect also the classes who resort to our universities, the values of the degrees conferred by them will be diminished by the nature of the associations at the cost of which they will be obtained. "The Oxford manner" may have passed into a joke, but we still have the right to expect as a result of the highest form of scholastic training some outward and visible signs of the qualities which such a training may reasonably be expected to confer. Vulgar rowdyism can never lead the way either to the acquirement of knowledge or to the practice of the politeness which smooths away so many of the difficulties and rough places of the world, which costs nothing, and which yields so abundant a harvest to those by whom it is practised.

Annotations.

"Ne quid nimis."

ON THE POSITION OF MATERIA MEDICA IN THE MEDICAL CURRICULUM.

THERE was a time when it was very necessary for almost all medical men, especially for all in general practice, to possess a fairly full knowledge of materia medica. They had to recognise the plants from which were obtained the drugs they administered; they had to be able to decide whether the crude drug presented to them was exactly the drug they wanted or something bearing a close resemblance to it. They had to know the method of preparation of the infusions, the decoctions, and the extracts which were the forms in which these drugs were finally administered. They had to know the right temperature at which the preparations had to be made; the boiling points of liquids, the solubility of substances, and the tests for purity of the drugs employed by them. Therefore, in those days now long gone by, it was but reasonable for the student of medicine to be expected to possess a very thorough knowledge of the articles entering into the materia medica. They were questioned on the methods of preparation of the drugs; they were required to know, even to the smallest ingredient, the composition of the various compounds and the relative proportions of the several constituents. They had to recognise by sight a very large number of crude and refined drugs and of natural and prepared salts. They were required to be fully acquainted with the various tests which each substance was expected to pass, and some examining bodies even required, in addition, that the student should be acquainted with the natural orders to which the botanical specimens belonged. It was, on the whole, a dry subject, difficult to learn and remember, and many were the devices invented to enable the student to fix in his memory the constituents of some of the more complex preparations. The knowledge that was obtained with so much toil was at one time doubtless of genuine benefit, but long after the actual need for it existed the examining boards in this country persisted in requiring it of candidates. At last came a reaction. The increasing extent of the sciences ancillary to medicine claimed more and more of the student's time; a greater and increasing portion of his curriculum was demanded for the study of physiology, of chemistry, of physics and biology; and those with whom rested the preparation of the courses of study of medical students looked round to see which of the subjects studied could be most conveniently jettisoned, and threw over materia medica. Taught as it was then, much of it had become useless and obsolete. In the older scheme of study materia medica was linked on to therapeutics; the student was taught the value of certain drugs in the treatment of diseases of which diseases he had no knowledge either as to symptoms, pathology, or

etiology. Therefore for the most part the examining bodies decreed that while materia medica was to be done away with for all intents and purposes, therapeutics was to be given a later place in the medical curriculum. Of this arrangement we do not complain, but there is some fear that the reform in the matter of materia medica has been carried a little too far. We would by no means return to the former methods of teaching materia medica. With the enormous strain that at present exists on the time and attention of the student of medicine it is hopeless to attempt the reimposition of such a dead-weight as was the old materia medica. But there is a middle course. We consider it would often be good for the student to have a wider knowledge of the substances he employs. It would give him a more exact idea of what he prescribes; it would free him from over-dictation at the hands of the pharmaceutical chemist. Medical men owe a vast debt to the products of the research, skill, and care which characterise so much of modern pharmacy, but it is not rare for the pharmacist to step beyond his rightful domain and to attempt to indicate to the prescriber what and how he should prescribe. We have no special wish to conserve the use of Latin in prescriptions, though it may ensure a prescription being understood and correctly compounded in every quarter of the globe, but a student at his qualifying examination should be able to write an intelligible prescription at least in English, containing the drugs suited for the effect which he wishes to obtain and so compounded that they are fit for administration. This is no unreasonable demand, and yet all who have to examine students for their final examinations will agree that the average medical student at the end of his course is frequently unable to write a prescription free from faults.

LONDON COWS FOR LONDON NURSERIES.

THE trouble of obtaining pure milk in London, especially when it is for the purpose of the feeding of infants, is so great that any attempts to improve the actual unsatisfactory state of affairs deserve notice. The fundamental difficulty in the matter is that the milk has to come from a distance, sometimes from quite a long distance, and from districts where the control exercised at the farm may be insufficient. It is apt, moreover, to deteriorate during the journey from causes to the enumeration of which we have devoted considerable space at different times. How can these things be avoided? Obviously by having cows in London, but London has not been constructed to embrace farm-lands in her boundaries. And cows, especially during the milder months of the year, should be out in the fields. Also, the safest place to milk a cow is in the open air. But it has been demonstrated in more than one city by numerous analyses that milk obtained from the well-controlled, stall-fed cows kept in town stables is actually purer than that which has been derived from the inefficiently controlled country farms. Thus the inferior system, rigorously and properly carried out, gives better results than the superior system carelessly and improperly applied. An attempt to carry on a small dairy farm in the heart of London has consequently attracted our attention, and recently we paid a surprise visit to the establishment of Mr. E. J. Walker, a dairyman in Sloane-street, who keeps his milch cows in stalls in Church-street, Chelsea. Mr. Walker stated that he only bought cows that have been through the tuberculin test and after their third or fourth calf, as this is considered the best milking time. The stalls in Chelsea we found clean and free from odour, while the cows were obviously in good physical health and condition. The great point is that these cows are milked from 4.30 to 6 in the morning. In ten minutes the milk is conveyed from the stable to the depôt in Sloane-street, where it is filtered and placed in sealed bottles. By 7 o'clock it is at the consumer's house. But it is no easy matter to keep cows in London. Not only is the space for stables difficult to find and the rents are almost prohibitive, but the cost of food is about doubled, the same holding good for hay. In such circumstances pure milk from a town stable must be much dearer. The ordinary West-end price for milk is 4*d.* per quart. The charge for fresh-drawn milk from the stall-fed cow, delivered in sealed, sterilised glass bottles is 6*d.* per quart, though when it is a question of feeding infants the extra cost may be an economy. Does the question arise practically whether it would be good to encourage the establishment on a large scale of model cowsheds or stables for the production of nursery milk? Such stables would have a milking-room attached where the milkmaid, in a spotless overall and with specially washed hands, would milk the cow, away from stable dust, into a sterilised and cooled pail, while the fullest sanitary control could be exercised over the milk in its transit from the London cow to the London nursery. Our view is that anything like the formation of many such establishments in London would be impossible. It may require a very long time to reform and satisfactorily control all the country farms that send milk to London, but this can be done. The establishment of stall-fed cows inside London to meet even a fraction of the nursery demand would be impossible. Here and there, however, enterprising people like Mr. Walker may succeed in providing what must be a luxury.

"KUATSU" AND THE "HEART REFLEX OF ABRAMS."

"KUATSU" is the method empirically practised by Japanese experts in "Jiu-jitsu" for restoring to consciousness those rendered temporarily insensible by any of the orthodox "knock-out" movements. It has been used in addition with success in unconsciousness from other causes, in sunstroke, and in the treatment of the apparently drowned. An interesting paper by Abrams in the *New York Medical Journal* of Oct. 29th attempts to explain the physiological basis on which the treatment rests, and reaffirms its efficacy. There are various ways of performing Kuatsu, that usually seen amongst coolies on board ship in the Far East being to prop the patient up, stand behind him, grasp his head between the hands, and strike his seventh cervical vertebra rhythmically with the operator's right knee. The method, however, used by the Kano school, and sanctioned by the Japanese Government, is to lay the patient prone, with arms extended at right angles to the body, and for the operator to kneel over him and rhythmically strike his seventh cervical spine with the butt of his palm, wrist extended, until consciousness returns. He is then propped up, and his arms worked in a circle, after which he is helped on his feet, and induced with help to walk about in order to stimulate respiration and circulation, it having been found otherwise that he is liable to lapse into unconsciousness again and die. Abrams explains the frequent efficacy of the proceeding by stating that it is the most certain method known of stimulating the heart reflex called after his name. The "heart reflex of Abrams" is a "contraction of the myocardium of varying duration which results when the skin in the precordial region is irritated by stroking, tapping, or friction." The contraction is easily seen by means of the Roentgen rays, and may be mapped out by careful percussion of the area of cardiac dulness. It involves both ventricles, especially the left, after cutaneous irritation, and persists for some little time after the cessation of stimuli in normal hearts and may be present for some hours afterwards in cases

of cardiectasis. Previous injections of pilocarpine increase the sensitiveness of the reflex. Abrams found when X ray photographs were taken before and after one case that without pilocarpine there was a contraction of the shadow outline of from 1 to 2 centimetres, whereas 30 minutes after the injection of a tenth of a grain of pilocarpine on stimulation the shadow contracted from 2 to 7 centimetres. The reflex, he states, can be elicited from various surfaces on the body, but experimentally the most effective site and method, he found, was when the seventh cervical spine was percussed. Exercises and baths will produce the reflex, and to this he attributes the success of the Schott treatment, affirming, however, that "more can be done in a few days by eliciting the heart reflex in cardiac insufficiency" by the Kuatsu method "than by months of the conventional Schott treatment." In cases of acute infective disease with accompanying heart failure he also advocates its use, relating his results with a lady suffering from apical pneumonia, accompanied by heart failure. Late one night he was summoned hastily by her medical attendant and found her cyanotic and pulseless. As a last resort concussion of the seventh cervical spine was resorted to, the fingers of the operator's left hand placed on the patient's spine being struck by the right clenched fist slowly and steadily for ten minutes. The cyanosis gradually went and slowly the pulse became perceptible. At intervals of two hours throughout the night the process was repeated and each time the cyanosis became less and the pulse stronger. Eventually she recovered. The spine of the seventh cervical vertebra corresponds to the third dorsal segment of the cord and to the third dorsal nerve which sends a large branch to the inferior cervical ganglion, from which the augmentor fibres of the cardiac plexus are derived. It is probably stimulation of these, and not of the vagus as Abrams suggests, that increases the force of cardiac contraction and tonicity. Experimentally, concussion with a small hammer has been found the most effective method; and it seems probable that, after all, the habit of smacking coughing cyanotic people on the back may have physiological as well as time immemorial sanction.

THE TARRED ROAD.

THERE is a suspicion in not a few minds that the tarred road is prejudicial to health. Tar gives off, it is asserted, especially under the influence of the warm rays of the sun, peculiar empyreumatic substances which irritate the respiratory tract at some point or another. We are not disposed to accept that any really serious cases based upon this theory have arisen. If they have, the slight mischief can have been only transitory, since very soon the tar forms with the dust of the road a firm surface in which, apparently, the tar constituents are permanently fixed. There seems to be some reason for thinking that there is a kind of chemical affinity between the ordinary material of the roads and tar, for after a few months the two seem to set in a way recalling the hardening of asphalte, the granite stones can then be loosened only with some difficulty and the dust is bound. It may be conceded that the process of tarring the road gives rise to inconvenience, and here and there it may cause irritation to the nasal passages and throat, but as soon as the surface mass has set we are confident that no complaint on grounds of prejudice to health can be fairly levelled against the innovation. On the other hand, there can be little question that the matured, firm combination of tar, stones, and dust is being widely appreciated wherever the method has been adopted. The only objection we have heard of is that the firm tarred road is objectionable to horses, which show signs of fatigue very much sooner on the hardened surface than on the ordinary road, the material of which, of course, yields to some extent to foot pressure. We can appreciate this objection, but possibly a remedy for this could be found in a modified form of shoe for the horse. The motor will not so rapidly displace the horse that a palliative of the kind suggested needs no serious consideration. On general sanitary grounds the tarred road, when efficiently done, has everything in its favour. It presents a surface practically proof against the soakage and accumulation of offensive matters; it is washed clean by the rain, and surface drainage into the gutters and gullies is more effective provided the surface is even. These are very important considerations, having regard to the pathogenic possibilities of road dumpings. While, therefore, the primary object of the tarred road was the prevention of the dust nuisance, the process has improved the conditions of our highways in other important sanitary directions. Lastly, the method is preserving the surfaces, it keeps the binding material, the dust, to the road, and prevents its reduction to a layer of grit glistening with sharp, flinty particles, which often tempted the cyclist to say ugly things of the motor. The cyclist is rapidly appreciating the tarred road; he finds in it a smooth, practically frictionless, surface to run over, and the chances of a puncture are considerably reduced.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

AT the festival dinner of the City of London Hospital for Diseases of the Chest, which was held at the Trocadéro Restaurant on Nov. 10th, the Hon. Walter Rothschild, who presided, entered a strong plea for increased financial support which is urgently required if the hospital is to keep its beds in full use. The chairman pointed out that less than 15 years ago the fortunes of the hospital had sunk very low and more than half the beds had to be closed. Owing, however, to the untiring energy of everyone connected with the hospital all the 170 beds were now occupied. This desirable state of things had only existed for one year, and the committee had been greatly encouraged in their efforts on behalf of the hospital by a gift of £4000 from the King Edward Hospital Fund. Hospitals had to live on their current income, and so long as people believed that it was only necessary to give a good sum of money at a hospital dinner so long would hospitals continue in an unstable position, but he hoped that the time would come when the charitable public would realise that the better plan was to endow hospitals. A remarkable feature in connexion with the hospital was the large number of working-men's societies which contributed more than £1000 a year. A matter which called for the earnest attention of all those who wished the work of the institution to be carried out in the best possible way was the provision of a sanatorium. It was not fair to the medical staff that after they had given unremitting care to a patient in the hospital the treatment should be nullified because there was no sanatorium where it could be continued for a few weeks with the object of completing the cure. Dr. George A. Heron endorsed the plea for a sanatorium, hoping that everyone who had the welfare of our consumptive poor at heart would see that a hospital like the one for which he was pleading, in the very centre of the East-end of London, should no longer remain without the sanatorium which it so greatly needed. It was hypocrisy, he said, to tell a poor patient to go to his own home and continue the hospital treatment, while the most dangerous class of consumptives were those who were unable to get continuous treatment, because they carried infection to other classes. Dr. T. Glover Lyon also emphasised the necessity for a sanatorium. In the course of the evening the secretary read a list of subscriptions amounting to £2617.

The contributions from various working-men's societies ranged from 30 to 200 guineas.

THE MEDICAL PROFESSION AND MUNICIPAL HONOURS.

THE following members of the medical profession have been elected or re-elected to the mayoral chair:—*Faversham*, Mr. S. R. Alexander, M.D. Lond., M.R.C.S. Eng., L.S.A.; *Hartlepool*, Mr. W. Scott Gibb, M.B., C.M. Edin.; *Montgomery*, Mr. N. W. Fairles-Humphreys, M.R.C.S. Eng., L.S.A. (re-elected); *Newark*, Mr. F. H. Appleby, M.R.C.S. Eng., L.S.A. (re-elected); *Oswestry*, Mr. R. de la Poer Beresford, M.D. Glasg., L.R.C.P., L.R.C.S. Edin., L.R.C.P. Lond. (re-elected); *Ruthin*, Mr. T. Owen Jones, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg. (re-elected); *Saffron Walden*, Mr. J. P. Atkinson, M.D. Glasg., L.R.C.P. Lond., L.R.C.S. Edin.; *Warrington*, Mr. G. W. Joseph, M.D. Durh., L.R.C.P. Irel., M.R.C.S. Eng; *Wrexham*, Mr. S. Edwards Jones, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg.

PNEUMOCOCCIC POLYARTHRITIS RESEMBLING RHEUMATIC FEVER.

PNEUMOCOCCIC arthritis has been rarely observed in this country, and has been principally investigated by continental writers. The first case recorded in England was published in our columns by Dr. E. J. Cave.[1] In adults the condition usually occurs in association with pneumonia, but in children it frequently occurs apart from the latter. Like many supposed rarities, pneumococcic arthritis is probably not so rare as its records might lead one to suppose, and would be more often observed if looked for. This is borne out by the fact that within the last two years no fewer than five fatal cases of pneumococcic polyarthritis have been under the care of Dr. Finley in the Montreal General Hospital. They are recorded in the October number of the *Montreal Medical Journal* by Dr. A. H. MacCordick, of the Pathological Laboratory, who calls attention to their resemblance to rheumatic fever. In all the diagnosis was proved bacteriologically. It is interesting that in four of the cases there was a previous history of rheumatic fever and in the remaining one of chorea In the first case, a girl, aged 16 years, was admitted on Oct. 8th, 1908, complaining of pain in the left shoulder and in the ankles. In childhood she had whooping-cough and measles. At the age of seven years she was in the hospital for two months with rheumatic fever involving the knee- and ankle-joints. At the age of 14 years she was again admitted with rheumatic fever and pneumonia. At the age of 15 years she was two months in the hospital with rheumatism of the left elbow and knee, and right ankle and knee. There was a mitral systolic murmur. Recovery took place under salicylates. During the summer before her present illness her feet and ankles were occasionally swollen and painful. Her illness began on Oct. 4th with pain in the left foot. On the following day this foot was better, but the right was involved. Three days later the left shoulder became very painful. The pain in the joints was of a sharp stabbing character and was felt only on movement. She vomited several times daily and perspired freely at night. On admission she was somewhat anæmic and drowsy. The temperature was 100·4° F. and the pulse 112. There was a diffuse cardiac impulse and the cardiac dulness extended to the second rib and 3 centimetres to the right and 13 centimetres to the left of the middle line. The first sound was replaced by a blowing murmur. The left shoulder and both ankles were very painful on movement, but were not swollen. The red corpuscles numbered 3,546,000 per cubic millimetre. On the 9th the pain in the joints was less, but there was severe pain in the præcordium, where a to-and-fro friction rub was heard. The temperature ranged from 98° to 102°. On the 11th there were signs of double pleural effusion. On the 13th the pulse was very feeble and small and she sank and died. At the necropsy 500 cubic centimetres of clear fluid were found in the peritoneal cavity, and 100 cubic centimetres of brownish fluid in the left pleural cavity. The pericardium contained about 50 cubic centimetres of brownish turbid fluid. The visceral and parietal layers were firmly adherent by a greyish fibrinous exudate. The heart weighed 375 grammes. The mitral valve was sclerosed and contracted and on its edges were a few small reddish vegetations. There was well-marked acute nephritis. The left shoulder-joint contained a little slightly turbid fluid, but the synovial membrane was smooth and glistening. Cultures made from the heart's blood, the pericardium, and the shoulder joint showed the pneumococcus. In the second case a girl, aged 16 years, was admitted on Feb. 27th, 1909, complaining of pain in the chest. She had been previously admitted three times for rheumatic fever. Her illness began on the 22nd, when the left ankle became swollen, red, and tender and painful on movement. On the following day pain in the chest began. In a day or two the ankle was better, but the pain in the chest continued. On admission the temperature was 101·4° F. and the pulse 120 and small. The præcordium slightly bulged. The cardiac impulse was in the left fifth and sixth spaces, 10 centimetres from the middle line. There were a mitral systolic murmur and frequent hacking cough, with little expectoration. Subcrepitant râles were heard at both bases and there was dulness below the left ninth rib. On March 2nd the lips and finger-nails were cyanosed, the face was pale, and the extremities were cold. She occasionally expectorated a little tenacious bloody sputum. There were occasional spasms of præcordial pain. Fine crepitations were heard all over the chest and there was some œdema of the ankles. She became weaker and died on the 4th. The necropsy showed left lobar pneumonia, chronic fibrinous pericarditis, and acute and chronic endocarditis. The synovial membrane of the left ankle-joint was normal, but the fluid in it, which was only sufficient to moisten a swab, as well as the heart's blood and the pericardium, showed on culture the pneumococcus. In four of the cases (including the two which have been related) the arthritis preceded other affections by an average period of about six days; in the remaining case it occurred three days after the onset of pneumonia. Lobar pneumonia was present in one case and bronchopneumonia in two cases. The patients were all females, and excepting one, aged 39 years, were children from the age of 14 to 16 years.

[1] THE LANCET, Jan. 12th, 1901, p. 82.

INVERSION OF THE RADIAL REFLEX.

UNDER the name of "Inversion of the Radial Reflex," M. Babinski, who is so well known by his eponymic plantar reflex, has added another pathological reflex to clinical medicine. At a meeting of the Société Médicale des Hôpitaux of Paris on Oct. 14th he reported this discovery. In the normal state percussion of the lower end of the radius usually produces simple flexion of the forearm on the arm. If the reflexes of the upper limb are strong other movements, particularly flexion of the fingers, may accompany flexion of the forearm. This generally occurs in hemiplegia of cerebral origin. But in health percussion of the radius never causes flexion of the fingers alone. This "inversion of the radial reflex" M. Babinski has found in certain diseases of the cervical cord—syringomyelia and tumour—but never in lesions of other parts. He has not had an opportunity of performing a necropsy in any case, but physiological data show

clearly where the lesion must be situated. The centre for the reflex of flexion of the forearm on the arm is situated in the fifth cervical segment, while that for flexion of the fingers is situated in the eighth cervical segment. The conclusion is obvious that inversion of the radial reflex is due to a lesion of the fifth cervical segment. In such a lesion reflex flexion of the forearm on the arm could be abolished, and if the lesion extended to the pyramidal tracts reflex flexion of the digits would be increased. M. Babinski admits that the same phenomenon could be produced by a limited lesion of the peripheral nerves, but he has no experience of a lesion of this kind, and if it occurs he thinks it must be exceptional. From his observations he draws the conclusion that inversion of the radial reflex constitutes a sign which by itself alone allows a lesion of the cervical cord to be affirmed, and points to its exact localisation.

THE SUPPRESSION OF RABIES IN PARIS.

THE report for the year 1909 of the Veterinary Sanitary Service of Paris and the Department of the Seine has just been issued. It is a big book, and as usual contains a great mass of detail concerning the prevalence of various diseases among cattle and animals of all sorts. The control of abattoirs and meat markets, the transport of fish and milk, in a word, some of the most important matters in the food-supply of the city come under notice. Of the various chapters, the first is in some ways the most interesting. It contains a history of the struggle to suppress rabies, which is still relatively widespread in France. This is all the more serious as there are more dogs in France than in most countries. Thus it appears that per 1000 inhabitants there are 75 dogs in France and only 38 in England, 31 in Germany, and 11 in Sweden. In England and Sweden rabies has been stamped out, and it is very rare in Germany. Dr. H. Martel, Chief of the Veterinary Service and author of the report, considers that the most useful measure is to destroy all stray dogs. This of late years has been done rigorously in Paris and the surrounding department of the Seine, but not so in the other departments or counties of France. Thus in the Seine, which includes Paris, there were 807 cases of rabies among dogs in 1900, and 1964 in the other departments. There had been 9691 dogs captured the previous year. In 1900 more than 12,000 were taken, and the following years the number of captures amounted to 16,298, 16,856, 14,665, and 15,251. This brings us to the year 1904. The result is that in 1901 there were 846 cases of rabies in the department of the Seine, and 1872 in the other departments; in 1902 the figures were respectively 474 and 1852; in 1903 there was a further fall to 179, while the figure for the departments rose to 2184. In 1904 and 1905 the figures for the departments were 2221 and 2248, while for the department of the Seine they were only 172 and 120. The decrease has continued, and in 1906 the number was 74, in 1907 only 43, in 1908 it was 37, and finally last year only 13 cases of rabies were reported, where at the beginning of the decade there had been more than 800. Surely this is a notable achievement. In the departments during the last four years there are signs of improvement, the figures having fallen to 1971, 1849, 1445 and 1450 for the four years in question. The amelioration achieved in the department of the Seine is set forth in another manner. In 1901 the tax was paid for 140,000 dogs, so that the proportion of cases of rabies was 0·604 per cent. of dogs taxed. In 1909 the tax was paid for 185,000 dogs, and as there were only 13 cases of rabies, this was equal to 0·007 per cent. Again, if we take the first five years of the decade—namely, 1900 to 1904—there were altogether during this time 2478 cases of rabies in the department of the Seine; while during the second five years, 1905 to 1909, there were only 287 cases. These figures are based on the notifications made by veterinary surgeons as the result of diagnosis or of post-mortem examination. In the former case errors sometimes occur. There is a tendency to be on the safe side and declare a dog to be mad so that it should be destroyed when after all it was not affected by rabies. As far as possible these declarations have been checked by post-mortem examinations or by inoculations, but this could not always be done. If only the cases proved genuine at the Pasteur Institute were counted the figures would be reduced by more than half, but the falling-off in the number of cases from year to year would be in the same proportion as that shown by the figures given above. Obviously the best protective for human beings is to keep the dogs healthy. This does not prevent persons who are bitten by perfectly healthy dogs from hastening to the Pasteur Institute to undergo the antirabic treatment. Therefore the number of patients treated does not represent the number of *bonâ-fide* cases of rabies among dogs. Nevertheless, there has been a great reduction of patients, though doubtless dogs are just as apt to snap and bite as in the past. At the Pasteur Institute 637 patients underwent the antirabic treatment in 1900 and 623 in 1901. In 1909 the number of persons treated because they had been bitten by dogs that might possibly be suffering from rabies was only 105. As for human cases of rabies these are extremely rare in the department of the Seine, the last one observed dating back to the year 1905. Formerly they were relatively frequent. Dr. Martel insists that the great improvement brought about is due to care taken, when a case of rabies occurs, to destroy not merely the mad dog, but further to destroy, or in any case to closely observe, all the other dogs it may have infected. As, however, this can rarely be done in complete manner, obviously the most effective measure is the capture of all stray dogs.

THE DISPENSING OF MEDICINES.

ATTENTION has been directed by a correspondent to a report of an address delivered by Mr. Richard Winfrey, M.P., whose name appears on the Register of Chemists and Druggists, at a meeting of the Public Pharmacists and Dispensers Association, in the course of which he said that: (1) authorities appointing dispensers to public institutions should be made to understand the difference between a man who had passed the minor examination of the Pharmaceutical Society and one who had merely passed the Apothecaries' Hall assistants' examination; and (2) the knowledge of pharmacy possessed by the ordinary medical practitioner is very slight indeed, and medical practitioners should not be allowed to dispense their own medicines under their present qualifications. With regard to the first point, it is not disputed by anyone competent to judge that the diploma granted by the Pharmaceutical Society is of greater value than that granted to assistants by the Apothecaries' Society, and there are, we should imagine, few authorities responsible for the appointment of dispensers who are not aware of the fact. The possessor of the superior qualification, however, expects quite naturally higher remuneration for his services than does the holder of the assistant's certificate, and very often for that reason vacancies are filled in some institutions by the appointment of dispensers with the latter qualification. In all the great London hospitals and in the majority of the larger provincial hospitals the dispensers appointed are qualified under the Pharmacy Act, and the same rule applies in many of the smaller institutions. In other cases the dispensing is done by holders of the Hall certificate under medical responsibility or by local chemists. In every lunatic asylum under the control of the London County Council in which a

dispenser is employed the dispenser holds the qualification of the Pharmaceutical Society. The appointment of Poor-law dispensers is subject to the approval of the Local Government Board, whose regulations require the person appointed to possess one of the following qualifications: (1) the Licence of the Society of Apothecaries; (2) the assistant's certificate of the Society of Apothecaries; (3) registration as an army compounder, R.A.M.C.; (4) registration under the Pharmacy Act, 1868; and (5) registration as a pharmaceutical chemist of Ireland. It is hardly necessary to point out that those applicants who hold the highest qualification usually obtain the appointments when vacancies occur. The second point raised by Mr. Winfrey involves a question of considerable difficulty; for obvious reasons it is quite impracticable for every medical practitioner to employ a dispenser and, under existing conditions, a very large proportion of medical practitioners could not possibly refuse to dispense medicines. If they did so there would be no one else to do the work. At the present time a joint committee of medical practitioners and pharmacists is considering whether it is possible to make any recommendations with regard to this very question. The committee is composed of ten medical practitioners appointed at the last annual meeting of the British Medical Association and ten pharmacists appointed at the last meeting of the British Pharmaceutical Conference, and if it is able to put forward reasonable suggestions as to how medical practitioners can be relieved of what the physicians of two centuries ago described as a "servile and laborious business" the profession will not be ungrateful. But for the present the medical profession must continue to dispense medicines, and, as we point out elsewhere this week, those responsible for the education of our medical students should see that they are duly educated to this end.

THE DRUG TREATMENT OF PULMONARY TUBERCULOSIS.

So much interest has of late years been centred round the sanatorium treatment of pulmonary tuberculosis, and still more recently round the use of tuberculin, that the use of drugs in this disease has received but comparatively little attention. In the present number of THE LANCET we publish two communications on the results obtained by the employment of potassium bichromate in the one instance, and of continuous antiseptic inhalations in the other. Dr. James B. Tombleson publishes six cases treated by potassium bichromate. The cases all exhibited advanced disease, nevertheless the results were uniformly good. This is certainly remarkable and indicates that further trial might be made by other observers. The method has the advantage of simplicity. The drug is given in doses of ¼ gr. (2½ minims of a 10 per cent. solution in water), either alone or in combination with a tonic mixture, such dose to be taken in a wineglass of water after food, at first twice and later three times a day. Dr. David B. Lees advocates the employment of continuous antiseptic inhalations. He has previously published the results in 30 cases of incipient or early pulmonary tuberculosis in which the treatment had been employed with success. He now gives the further progress of these cases and shows that they continued to progress favourably. In his present article he reports 20 more cases in which the same method of treatment has been used. Some of these patients came under observation at a much later stage of the disease, nevertheless the results were all favourable. As Dr. Lees remarks, however, when the more advanced stages are reached recovery must be comparatively slow and the final issue may be doubtful. He strongly insists that pulmonary tuberculosis is recognisable and ought to be discovered before there is any breaking down of lung tissue, and adds: "To suspend the diagnosis until tubercle bacilli are detected in the sputum is like delaying the diagnosis of cancer until the glands are involved." Undoubtedly the earlier treatment is commenced in cases of pulmonary tuberculosis the better the prognosis, but it is difficult definitely to appraise the value of any treatment until the diagnosis of the disease has been absolutely confirmed by bacteriological evidence. There is always a possibility of doubt that active tuberculosis was not present. Dr. Lees's method of treatment should be extensively tried, for his results are decidedly encouraging, and the fact that relief can be obtained in other than very early cases is a stimulant for further observations to be made. In THE LANCET of Nov. 12th we published an article by Mr. J. McElroy on the treatment of pulmonary tuberculosis by intravenous injections of chinosol with formaldehyde. He recorded three cases in which this method was adopted, and in which satisfactory results were obtained, but the number of cases is, of course, too small to form a judgment upon. These several therapeutic measures might be further tried in those cases in which, for various reasons, sanatorium or vaccine treatment cannot be adopted. It would be interesting to know whether other physicians obtain the same results as those who have recorded their cases in our columns.

THE MARKING OF IMPORTED MEAT.

THE Local Government Board has recently issued a circular addressed to medical officers and sanitary authorities calling attention to the description of a brand and labels which are declared to be admissible as "official certificates" in respect of pork and other edible portions of the pig which have been subjected to inspection in the State of Queensland. The labels, facsimiles of which are reproduced in the circular, are regarded as evidence that the pig has been certified by a competent authority in the place of origin to be free from disease at the time of slaughter. The labels are taken to convey also that the meat has been certified by the like authority to have been dressed or prepared, and packed with the needful observance of all requirements for the prevention of danger arising to public health from the meat as an article of food. The Local Government Board takes the opportunity afforded by the issue of the circular of pointing out that difficulty has been experienced in some cases in extracting from the annual reports of medical officers of health certain details which the Board desires as to quantities of food materials condemned at the ports. In some of the annual reports the required facts are given with considerable fulness, but in others, although much useful information is set out in regard to this matter, details are not recorded in a form which enables them to be properly classified. The circular contains a category of the foods concerned and the kind of particulars which should be given.

PLAGUE AND THE DESTRUCTION OF RATS.

THE Local Government Board, in consequence of cases of plague in rats in certain parts of England, has deemed it desirable to confer upon local authorities in England and Wales powers with regard to the destruction of rats in districts where plague in rats is present or suspected, or in which there is an unusual mortality among rats. The Board has accordingly issued an Order authorising the local authority to take measures for the destruction of rats and for preventing their entrance into buildings and any premises. Inasmuch as the risk of infection from plague-stricken rats arises mainly through fleas, it is obviously to the interest of all persons to do what they can to prevent contamination of their dwellings and to remove from the proximity of dwellings

accumulations of material or rubbish which may harbour rats or their parasites. A memorandum on plague has been prepared by the Board's medical officer and is now issued, and the Board has arranged for bacteriological testing of material from the earliest suspected case or cases of plague or from the earliest suspected rodents in any district. This material can be received by the Board only from the medical officer of health.

PARLIAMENT reassembled on Tuesday, Nov. 15th, but in the present state of public affairs it is fairly certain that no medical questions will be considered.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Nov. 10th, Mr. BUTLIN, the President, being in the chair.

In accordance with a report from the Court of Examiners Diplomas of Membership were granted to 66 successful candidates and Licences in Dental Surgery were issued to five successful candidates.

The Council accepted the tender of Messrs. Holland and Hannen for the building of the Examination Hall in Queen's-square.

A letter was read from Mrs. Langton thanking the Council for their resolution of sympathy on the death of her husband.

The PRESIDENT reported that the Bradshaw Lecture would be delivered by Sir A. Pearce Gould, K.C.V.O., on Wednesday, Dec. 7th, at 5 P.M., and that the subject of the lecture would be Cancer.

The PRESIDENT reported that Mr. Bruce Clarke's period of office on the Court of Examiners would expire in December next, and that the vacancy thus occasioned would be filled at the ordinary meeting of the Council on Dec. 8th.

The SECRETARY reported the delivery of three Museum demonstrations by Dr. Arthur Keith and three by Mr. S. G. Shattock.

A vote of thanks was accorded to Mr. Lockwood for a gift of books.

WOMAN SUFFRAGE: THE CONCILIATION BILL.

THE following memorial was sent to the Prime Minister on Nov. 14th, 1910, signed by 407 medical women:—

We the undersigned medical practitioners desire to urge the Government to grant immediate facilities for the further stages of the Conciliation Committee's Bill for Woman Suffrage.

In a Memorial which 538 medical women had the honour to present to you in November, 1908, their unanimity on the question of woman suffrage was clearly shown.

As members of the medical profession women conform to all regulations imposed upon candidates for medical degrees, and they undertake responsible public and private work which is fully recognised by the State. It is manifestly inexpedient that, on the ground of sex alone, they should be unable to influence legislation on questions about which their special knowledge particularly fits them to hold an opinion.

Moreover, as taxpayers, women practitioners feel strongly that their exclusion from all voice in the election of Parliamentary representation is inconsistent with the first principles of democracy, viz., that Government rests on the consent of the governed, and that those who pay the taxes should have a voice as to how the taxes are spent.

The justice of the claim made by women for the parliamentary vote has been admitted by large majorities in the House of Commons on many occasions.

We urge that the dignity of the House of Commons will be diminished if it fails to put its principles into practice. We ask that time may be given to allow the present House of Commons to carry through the final stages of the Conciliation Bill, which has already passed its second reading by a majority of 110 votes and which proposes to extend the Parliamentary franchise to those women who are already on the municipal register.

The majority of medical women, as householders, would be enfranchised by the Bill.

TORQUAY NURSES' INSTITUTION.—As a result of the fête recently held at the Princess Gardens the sum of £280 has been raised for the Torquay Nurses' Institution.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Board of Education and Accommodation for Defective Children.

THE Board of Education, in granting for a limited period an application by the London County Council for recognition of a temporary building as a school for mentally defective children, has intimated that it strongly deprecates makeshift arrangements for providing education for defective children in London, and urges the Council to proceed with all possible despatch to complete the survey of accommodation. The survey should include schools for physically defective, as during the year ended March, 1909, 11 schools for mentally defective and 11 for physically defective children were seriously overcrowded, deductions having to be made from the grant on this account. Similarly during the year ended March, 1910, so far as the review of claims for grant had gone, seven schools for mentally defective and 11 for physically defective children had been found to be overcrowded and the grant had been reduced in some cases. The Board hoped the Council would take steps to put matters on a satisfactory footing without delay.

The Education Committee, in reply, stated in a report presented to the Council on Nov. 15th, that a survey of the accommodation for mentally defective children had been made, and proposals for providing 705 additional places to meet immediate needs had been submitted to the Finance Committee. That committee suggested that the first question to decide was the principle involved in the provision of additional permanent accommodation for mentally defective children pending the result of the deliberations on the report of the Royal Commission on the Care and Control of the Feeble-minded—still under the consideration of the General Purposes Committee. In the circumstances the Finance Committee had adjourned the consideration of the Education Committee's proposals.

Administration of the Provision of Meals Act.

The Board of Education has asked for a return with regard to the administration of the Education (Provision of Meals) Act, 1906, and for the observations of the Council on the following points: (1) The extent to which the provision of meals has appreciably increased the ability of children to take full advantage of the education provided; and (2) the extent to which the conduct and manners of the children have benefited under the discipline employed. The Board stated that it attached great importance to the close association of the work done under the Act with the work of the school medical service, and desired to be fully informed of the arrangements for securing coöperation between the school medical officer and the care committees and their officers, and in respect of the recommendation and selection of children, the regulation of the dietary, and the observation of the physical and hygienic results attributable to the meals.

The Education Committee suggested that a reply should be sent to the Board stating that the general appearance of the average necessitous child had been improved by the supply of school meals. To arrive at any estimate of the comparative ability of children was difficult, however, as under the Council's scheme children were not allowed, except during holidays, to remain unprovided with food. With a view to educating the children to be well-behaved, a list of rules of conduct had been drawn up. Where voluntary supervision was not forthcoming paid supervisors were to be employed. As to the nutrition of children there could be no absolute standard. Necessitous children were not necessarily ill-nourished at the time of application for aid, nor did they always need medical inspection. Malnutrition might be due to the absence of suitable food, or to such home conditions as overcrowding, lack of sunlight and insufficient sleep, which contributed to produce the typical appearance of a necessitous child. Consequently the care committees relied to a great extent upon the circumstances of a family as revealed by investigation. No hard-and-fast rule as to "necessity" had been adopted, so varying were the circumstances that almost every case had to be considered on its individual merits. In some cases the child remained ill-nourished although sufficient food seemed to be available. This might be due to insufficient building up of the tissues

either from unsuitable food or from lack of power to digest food—as in cases of bad teeth or indigestion. Other causes were: partaking of materials hindering digestion—strong tea for instance—or lack of power to assimilate food, as in cases of chronic irritation or tuberculosis of the lymphatic system. Excessive breaking down of the tissues occurring in conditions of nervous irritability, such as accompanied insufficient sleep, the attacks of vermin, chronic fatigue and overwork, and constant, though perhaps slight, febrile illnesses, also led to children having an ill-nourished appearance. Such cases came within the purview of the school doctor. There was always coöperation between the public health department and the education service through the medium of the teacher. The records of the school medical inspections were always at the disposal of head teachers and care committees, and were consulted when children were selected to receive meals. The head teacher indicated to the school doctor the children who appeared to be in need of special treatment, and the school doctors, on the other hand, often recommended inquiries into the home circumstances of individual children. In cases of delicate or anæmic children a dietary of milk or cod-liver oil was recommended by the school doctor, and if the case was approved this was supplied at the Council's expense. The *menus* for the school meals had been drawn up in consultation with the school medical officer.

Premiums on Pauperism.

A naïve request has been made to the London County Council by the Hampstead board of guardians, whose clerk wrote in the following terms:—

> The officers of the guardians take considerable care to inquire into the ability of relatives to support inmates of the asylums, and the collector of the guardians is paid by commission upon the amounts that he collects. The practice of your Council to take over any case where the relatives are found to be able to pay the full amount of cost of maintenance deprives the collector of his commission on the amounts so collected. Would it not be possible for the County Council to make provision for the payment of commission in such cases?

The request of the guardians, as the Asylums Committee pointed out to the London County Council on Nov. 15th, means practically that in order that the parish collector may draw his commissions, asylum patients, the cost of whose maintenance is not borne by any public authority, shall remain under the stigma of pauperism. For, so long as the payment for a patient's maintenance is made to the County Council by a board of guardians—no matter if the whole cost is recovered by the guardians—that patient remains a pauper. If, however, the expenses of maintenance are paid directly to the asylum without the intervention of a board of guardians, the patient ceases to be "chargeable to a union," and is classified as a private patient. It is the duty of the County Council to inquire as to the means of patients and to classify them as "private" if they are so entitled. Readers will find in the case of Regina *v.* Jones, *re* Stennett, a decision bearing on this point. The Council, not unnaturally, decided that it could not grant the Hampstead parish collector a commission on work he no longer performed.

Recovery of Cost of Dental Treatment.

An experimental scheme for the recovery from parents of the cost of dental treatment came before the Education Committee at its meeting last week, but was withdrawn by the chairman of the subcommittee concerned. The subcommittee remarked that in fixing a charge for dental treatment it had to be borne in mind that unless there was actual suffering parents generally did not recognise at present the need for treatment. The obligation the council was under to make a charge might militate against dental treatment being obtained, and until the importance of dental treatment was more widely recognised it was desirable that the inducements for obtaining it should be as great as possible. The subcommittee thought that as an experiment the following inclusive charges should be made: 2*s.* 6*d.* for the complete treatment of the mouth where stoppings were included; 1*s.* 6*d.* where the treatment consisted of extractions under gas; and 6*d.* for simple extractions. Where more than one child in a family required dental treatment half the amount charged for the first child should be charged for each additional child, provided the net family income was 25*s.* or under. Legal proceedings to enforce payment would not be taken where the net income fell below 17*s.* 6*d.* a week, and in the case of incomes below 30*s.* remissions would be made according to circumstances.

THE CHOLERA EPIDEMIC.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Cholera in Russia.

SINCE the date of my last letter on this subject (which appeared in THE LANCET of Oct. 15th, p. 1160) there has been a continued decline in the epidemic of cholera in Russia. I give below the "corrected" figures for the last three weeks (August 15th to Sept. 4th, Old Style), for which "uncorrected" figures were given in that letter:—

Week ending August 21st ...	13,330	cases,	6,187	deaths.
,, ,, ,, 28th ...	9,962	,,	4,924	,,
,, ,, Sept. 4th ...	5,895	,,	2,853	,,

Since then the "uncorrected" figures for four weeks have become available. They are as follows:—

Week ending Sept. 11th ...	3038	cases,	1474	deaths.
,, ,, ,, 18th ...	2104	,,	1087	,,
,, ,, ,, 25th ...	1677	,,	858	,,
,, ,, Oct. 2nd ...	679	,,	353	,,

(The above dates are all according to the Old Style.) During these seven weeks the epidemic has been most active in the governments of Samara, Saratof, and Voronezh in the Volga valley; in those of Kief and Ekaterinoslav; in the province of the Terek and the governments of Tiflis, Daghestan, and Erivan in the Caucasus and Transcaucasia; in the Don Territory; and in the Orenburg government. It may be noted that the single cases formerly reported from the governments of Archangel, Olonetz, and Pskof have been succeeded by several others, though the totals for these governments still remain very low. In Reval, also, some further cases have occurred, and Riga (whence only 2 cases had been reported) has been the scene of a small epidemic. For Finland also the former total of 2 cases has now risen to 4. The Baltic province of Courland has appeared for the first time in the lists, but with very few cases. In Central Asia and Siberia all the governments and provinces formerly mentioned are still included in the returns; and, in addition, the disease has appeared in the government of Semipalatinsk, in the province of Ferghana (beyond Samarkand), and in the Far East provinces of Transbaikalia and the Amur. In each of these some scores of cases of the disease have been recorded. It will be seen, therefore, that practically the whole of Asiatic, as of European, Russia has been invaded by the cholera infection. In nearly all parts, however, the latest returns indicate a distinct and steady decline in the numbers of cases and deaths, and with the advent of the cold weather an early extinction of the epidemic may be looked for. It would be idle, however, to pretend that this can be more than a temporary extinction, and a fresh and possibly more severe revival next year must be regarded as highly probable, if not an absolute certainty.

The following observations, relating to the spread of the disease by water, may be quoted from the *Vratch*, in which they appeared at intervals during the last few months. As early as May it was reported that in samples of water taken from the river Dnieper at Kief large numbers of cholera vibrios had been found. The samples were taken from the river close to the intake of the town water-supply. At the same time many cases of cholera were occurring on the rafts plying on the river, as well as in the town. A month later it was stated that the same observer had found cholera bacilli in samples of water taken from streams flowing into the Dnieper in the outskirts of Kief—streams in which, it was added, the people washed, not only their clothes, but also fruit intended for the market. In Tiflis cholera vibrios were detected in the town water-supply (apparently in July), and the rapid spread of the disease there is said to have had all the characteristics of a water-borne epidemic. In Rostof-on-Don the same thing was observed. In Tashkent, in Central Asia, cholera vibrios were found in the irrigation canals which intersect the town. In Vladikavkay, in the northern Caucasus, cholera vibrios were found in the waters of the river Terek. At Biélgorod, in the Kharkof government, the bacilli were found in the waters of the river Donetz, a large tributary of the Don. Finally, in St. Petersburg, in three samples of water taken, on August 14th, 16th, and 17th (Old Style), from the stopcock at the water-works on the south side of the Neva, cholera vibrios

were found in all. Of three samples taken on the same days on the north side of the river bacilli were found in one. Of 22 samples of unfiltered water taken from the wells and tanks at the principal waterworks of the city on the same dates cholera vibrios were found in 9 (or 41 per cent.). Of 59 samples of filtered water taken at the same time from different filters and cisterns 11 (or 19 per cent.) were found to contain cholera vibrios. From another series of experiments it was shown that the filter-beds, as worked in St. Petersburg, only removed about 33 per cent. of the bacteria of all sorts contained in the Neva water. The above experiments were continued; and between August 18th and 23rd (Old Style) out of 23 samples of unfiltered water from the central waterworks, 16 (or 70 per cent.) were found to contain cholera vibrios; and out of 63 samples of filtered water from the same works 20 (or 32 per cent.) were similarly contaminated.

Cholera riots and disorders have been reported from many parts of the country.

Cholera in Germany.

I regret to have made an error in my last letter on this subject in stating that cholera had, up to the date of that letter, appeared in Germany solely at Spandau. As a matter of fact, as early as June 21st a Russian subject fell ill with the disease at Ruhleben, in the Potsdam district (a centre of control for immigrants). The result of a bacteriological examination in this case was positive. Three days later a second case occurred under precisely the same conditions; both patients died. The Spandau cases, already referred to, occurred in the last week in August. No other cases were seen there, though three carriers of bacilli (in addition to the four mentioned in my last letter) were detected. On Sept. 9th a boatman fell ill with cholera at Freiburg (district of Stade). On the 10th a labourer at Copitz, in Saxony, was attacked with the disease. On the 13th a second patient (the son of the above-named boatman) fell ill at Freiburg, and died. On the 13th and 15th there were three cases of the disease at Marienburg, in West Prussia (a shop assistant and two children). In the week ending Sept. 25th there were 5 cases and 2 deaths at Kalthof and Marienburg. On Sept. 22nd a death from cholera occurred at Sommerau, near Altfelde. In the week ending Oct. 2nd 4 more cases were recorded at Marienburg. In that ending Oct. 9th there were apparently 6 cases of the disease among persons under surveillance, as "contacts" of previous cases at Marienburg, and 1 of these died. Cholera bacilli were found in all of them; 2 were women and 4 were children; in addition, 2 children were found to be carriers of bacilli. Finally, for the week ending Oct. 16th no further cases were recorded in Germany.

Cholera in France.

Imported cases only have been seen in France. The ss. *Bosphore* arrived at Marseilles from Constantinople, and on Oct. 1st 3 undoubted cholera cases were isolated from among her passengers. On the 6th a fourth case occurred. There was, however, no spread of the disease to the inhabitants of Marseilles, which was consequently never regarded as an infected port.

Cholera in Austria.

No further cases of cholera have occurred in Vienna, and on Oct. 15th Austria was declared free from the disease as from Sept. 27th.

Cholera in Hungary.

The figures for Hungary were brought down in my last letter to the week ending Sept. 24th. For the following week the figures are wanting. Between Oct. 1st and 8th there were 34 cases with 13 deaths in 24 different places in Hungary; and the totals down to the last-named date were put at 207 cases and 106 deaths. In the week ending Oct. 15th there were 76 further cases and 34 deaths. Finally, on the 17th it was announced that a violent outbreak of the disease had occurred in the commune of Bata, in the province of Tolna, situated "on a branch of the Danube, the waters of which are stagnant," and that 31 cases had already been registered. (It should be added that 23 of these cases were included in the above total of 76 cases for the week ending Oct. 15th.)

Cholera in Italy.

Since the date of my last letter there have been reported, on Sept. 22nd, 12 cases and 2 deaths at Molfetta, 2 cases and 2 deaths at Trinitapoli, and 2 cases at Cerignola; and on the 23rd 6 cases at Molfetta, 2 deaths at Barletta, 1 case at Trinitapoli, and 4 at Cerignola. For the following week the figures are wanting. Between Oct. 1st and 11th 285 cases of cholera with 81 deaths were returned for the whole of Italy. The infected provinces were those of Avellino, Caserta, Bari, Foggia, Naples, Rome, Salerno, and Sassari (in the last-named only 3 cases occurred, on a ship in the quarantine station). In Naples itself as many as 104 cases, with 38 deaths, were recorded, and a long list of infected places in the Naples province appears in the return. At Rome 2 cases occurred. In the period between Oct. 12th and 19th (both included) there were 237 cases and 120 deaths for the whole country. Of these, 76 cases and 44 deaths are stated to have occurred in a lunatic asylum at Aversa, near to Naples; 53 cases and 36 deaths in Naples itself; and most of the rest in the provinces of Caserta and Naples. Four imported cases (not included in the totals) were observed in Rome.

Cholera in Servia.

On Oct. 12th a case of cholera was reported by telegram from Belgrade; as it was spoken of as "a fresh case" it was presumably not the first. On the 23rd 2 further cases were recorded. No further details have yet been received as to the occurrence of cholera in Servia.

Cholera in Roumania.

On Oct. 4th and again on the 7th single cases of cholera were reported from Tultcha, at the apex of the delta at the mouths of the Danube. No other cases of the disease have been reported from any part of Roumania since the date of my last letter.

Cholera in Constantinople.

The following are the returns of cholera among the civilian population of this city since the outbreak began on Sept. 13th.

From Sept.	13th	to Sept.	26th	.....	22	cases,	9	deaths.
,,	,,	27th ,, Oct.	5th	.....	50	,,	30	,,
,, Oct.	6th	,, ,,	10th	.....	12	,,	7	,,
,,	,,	11th ,, ,,	17th	.....	10	,,	8	,,
,,	,,	18th ,, ,,	24th	.....	7	,,	7	,,

No case has been recorded since the last-named date, but one fatal case (of earlier date) has been added to the list, making in all 102 cases and 62 deaths. Until Oct. 26th no mention was made in the bulletins of the occurrence of cases among the troops. But on that date it was suddenly announced that 200 cases with 92 deaths had occurred in the men of the 1st Army Corps (which form the Constantinople garrison) between Sept. 27th and Oct. 23rd. There have consequently been over 300 known cases and over 150 deaths from the disease in this city in the last five weeks. The outbreak seems now to be subsiding, but the danger of a revival of the disease next year cannot be overlooked.

Cholera in Asiatic Turkey.

There has been a considerable decline in the epidemic of cholera in the vilayets of Erzerum and Van in the last four weeks. It will be recalled that in the week ending Sept. 22nd as many as 224 cases, with 138 deaths, were reported. The following are the figures for the succeeding weeks:—

Week ending	Sept.	29th	.....	145	cases,	96	deaths.
,,	,,	Oct.	6th	.....	61	,,	43	,,
,,	,,	,,	13th	.....	13	,,	13	,,
,,	,,	,,	20th	.....	23	,,	22	,,

These figures bring the totals from the beginning of the outbreak on August 22nd to 543 cases, with 365 deaths. From consular reports, however, it becomes clear that these figures are considerably—and probably very greatly—below the truth.

Consular reports from the vilayet of Mamouret-ul-Aziz, of which Diarbekir is the centre, show that the disease reached there early in September; on the 6th of the month 5 cases occurred in a village three hours from Diarbekir; and some further cases followed. Later and more detailed news is still lacking for this vilayet.

The following are the returns for the town and vilayet of Trebizond since the beginning of the epidemic:—

From Sept.	16th	to Sept.	25th	.....	127	cases,	64	deaths.
,,	,,	27th ,, Oct.	3rd	.....	163	,,	98	,,
,, Oct.	4th	,, ,,	9th	.....	90	,,	40	,,
,,	,,	10th ,, ,,	16th	.....	109	,,	60	,,
,,	,,	17th ,, ,,	23rd	.....	23	,,	21	,,

Here also the figures must be accepted with great caution. The totals are put at 512 cases and 283 deaths.

The outbreak of cholera in the port of Zunguldak, on the Black Sea (the port for the coal mines of Heraclia), has not subsided, as shown by the following figures :—

From Oct.	1st	to Oct.	5th	.....	17	cases,	8	deaths.
,, ,,	6th	,, ,,	10th	.....	14	,,	7	,,
,, ,,	11th	,, ,,	16th	.....	12	,,	9	,,
,, ,,	17th	,, ,,	23rd	.....	20	,,	7	,,

The totals have therefore been 63 cases and 31 deaths.

On Oct. 8th news was received of the appearance of cholera at Khanikin, on the Turkish side of the Turco-Persian frontier; the first case apparently occurred on the 6th. Between that date and the 12th 8 cases and 8 deaths were recorded, followed by 2 other fatal cases before the 21st. Between the 17th and 22nd 7 other cases, with 4 deaths, occurred in the frontier lazaret at Khanikin. About this time cholera had appeared at Bagdad and at several other places along the Tigris Valley. At Bagdad the first 2 cases occurred on the 16th; down to the 23rd 34 cases and 26 deaths had been reported. At Shahraban 69 cases with 55 deaths, at Samara 17 cases with 15 deaths, at Kiazimieh 20 cases with 16 deaths, and smaller numbers elsewhere had occurred in the vilayet of Bagdad down to Oct. 23rd, bringing the totals to that date to 199 cases with 148 deaths. Several of these occurred in the temporary lazarets opened along the course of the river.

No indigenous cases have yet been reported from Syria; but on Oct. 17th and 18th two boatmen at Beirût, who had assisted in landing a batch of pilgrims from a Russian steamer (the s.s. *Voronezh*) fell ill with typical cholera (confirmed bacteriologically). It is remarkable that no known case of the disease had occurred among the pilgrims themselves. The ship had come from an infected port, and had undergone quarantine and disinfection in the Turkish lazarets. The boatmen were themselves in quarantine in the Beirût lazaret when they developed the disease. The infection did not spread outside the lazaret.

The first certain cases at Basra, near the head of the Persian Gulf, were reported on Oct. 21st, when 3 cases, 1 in a person who had come from Bagdad, were registered. On the 26th 5 cases and 3 deaths occurred there, and on the 27th 5 cases, with 4 deaths.

Cholera in Muscat.

On Sept. 21st news was received here that cholera had broken out at Muscat; down to the 24th 17 cases, with 13 deaths, had been recorded. In the following week there were 6 cases, with 4 deaths. On Oct. 10th the port was declared cholera-free, but on the 23rd the disease was again reported present; 5 further cases, with 4 deaths, had occurred.

Cholera in Persia.

On Oct. 6th 7 cases and 5 deaths from cholera were reported from Kermanshah, on the Persian side of the Turco-Persian frontier. The disease broke out here almost at the same time as at Khanikin, on the Turkish side of the frontier. The disease spread rapidly; by the 11th 67 cases, with 46 deaths, had been registered. In the week ending the 17th 227 deaths from cholera occurred in this by no means large town, and all places situated between Hamadan and Kasrisherin were said to be infected. In the following week the cholera mortality sank to 107. Information as to the course of the epidemic in other parts of Persia is still very scanty, but the disease has been, or is, present in Meshed, at Badjnuiran in Khorassan, at Ardebil and Sorab in the Tabriz neighbourhood, and at Enzeli on the Caspian. At Meshed the disease appeared on Sept. 11th, and in three days 28 cases with 8 deaths had occurred.

Cholera in Tripoli (Africa).

The first known cases of cholera here were seen on Oct. 3rd, when two Jewish women in the Israelitish quarter of the town fell ill; 5 other cases occurred in the same house, and 4 of the 7 cases died. The disease spread elsewhere in the town; by the 20th from 4 to 8 cases were being reported daily; on the 26th the number rose to 13, and on the 27th to 16 cases, with 10 deaths. Next day there were only 11 cases with 7 deaths, and finally, on the 29th, 4 cases and 4 deaths. The source of the infection in Tripoli is unknown; but there is frequent communication between its shores and those of Italy, and the first rumour of cholera was the occurrence, on Sept. 15th, of two suspicious cases on an Italian steamer which arrived in Tripoli from Italy; later, however, these were stated to have been cases of gastro-enteritis.

Cholera in Tunisia.

The only appearance of cholera in Tunisia that has been officially announced has been the occurrence of a few cases in the island of Jerba, not far from the Tunis-Tripoli frontier. On Oct. 3rd 2 deaths from cholera occurred here; on the 5th there were 2 more cases in the same house; between that date and the 25th no news was received, but on the last-named date there were 7 cases and 6 deaths.

Conclusion.

From the above brief summaries of reports from many countries it will be seen that the infection of cholera is or has been recently extremely widely spread; it has caused a more or less high mortality throughout (practically) all European and Asiatic Russia, extending from the Baltic and White Seas to the Pacific; it has been present, and in some places fairly active, in Germany, Austria, Hungary, Bulgaria, Roumania, Servia, Turkey in Europe, Asia Minor, Mesopotamia, Persia, the sultanate of Oman (Muscat), and in Tripoli and Tunisia on the north shores of Africa. The coasts of the Mediterranean, Sea of Marmara, the Black Sea, and the Persian Gulf (for Basra is close to the waters of the Gulf) have all been invaded by the infection, and it will be surprising if the germs of disease thus widely spread do not next year, and perhaps for years to come, give rise here and there to recurrent epidemics of greater or less severity.

Constantinople, Oct. 29th.

THE PHYSICAL EFFICIENCY OF RESERVISTS.

IN THE LANCET of Nov. 5th, pp. 1377–8, there appeared a report on the "Recent Army Manœuvres in the South of England" by "A Special Correspondent," the concluding paragraph of which has been taken exception to by our contemporary the *United Service Gazette* on p. 367 of its issue of Nov. 10th under the heading "The Special Reserve and Militia." The paragraph in question ran as follows :—

> Two classes of reservists were mobilised with the Second Aldershot Division, army reservists and special reservists. It was noted that many of the former were men of more or less advanced life and unfit for the arduous daily marching; many more suffered from advanced dental caries. Amongst the special reservists the opposite extreme was notable; many of these were mere boys and quite physically unfit to march the distances covered by the troops. In one column alone some 250 reservists were reported as having been so incapacitated by the marching that it was found necessary to transfer them to the Base Hospital at Aldershot. Such an occurrence as this becomes all the more grave when it is considered that the climatic and other conditions under which the army manœuvres occurred were so favourable. The weather was all that could be desired and the marches were not excessively long, the rations were generous, and tents were used almost every night. What would have been the experience under adverse conditions?

This paragraph, the *United Service Gazette* complains :—

> is couched in such vague, incoherent terms that it is likely to give rise to a good deal of misunderstanding and to play into the hands of that prejudiced body who never miss an opportunity of throwing a stone at the Special Reserve and the Territorial Force, in furtherance of their gospel of compulsion.

Our critic continues :—

> Now to the conundrum which THE LANCET propounds we have no objection to offer, inasmuch as it is serious to contemplate what would happen in the case of actual hostilities, when such casualties occur in the piping times of peace. But what we have to complain of is the reckless, ambiguous way in which THE LANCET sums up the situation. After dealing with the two groups of Reservists separately, in terms the reverse of complimentary, THE LANCET lumps them together in figuring out the casualties. And this is where inexcusable carelessness comes in, for an authoritative organ of this description having found little difficulty in obtaining the exact number of casualties, could easily, had it been so minded, have gathered separate statistics for each body and so have differentiated between them. It was of the highest importance that this should have been done, not only as an act of common justice to the Special Reserve, but also in fairness to the Regular Reserve. As it is, either is suffering from the stigma attaching to the other. Sweeping statements of a general character are always to be regarded with profound suspicion as they may mean anything or nothing, and are usually unreliable. Specific statements giving concrete instances are, on the other hand, of value, as they afford means of direct investigation with resultant confirmation or refutation.

Our answer to the charges of vagueness, incoherence, recklessness, ambiguity, and so on is that the statement is specific and coherent and in no way reckless or ambiguous. The statement on analysis stands: "That in the Second

Aldershot Division some 250 reservists were reported as having been so incapacitated by the marching that it was found necessary to transfer them to the base hospital at Aldershot." Our Special Correspondent stopped where he did because he was reporting to us under our instructions upon the medical aspect of these manœuvres and the physical aspect of the men as a whole.

The *United Service Gazette* goes on to say:—

In the present instance having nothing definite to go upon we yet took the trouble to inquire into the case of at least one Aldershot corps that had its special reserve battalion attached to it throughout the manœuvres. That particular unit was the 1st Battalion Royal Irish Fusiliers, whose 3rd battalion was brought over from Armagh and joined forces with the regular unit as a composite battalion for manœuvre work. Not a solitary man of this Special Reserve unit "fell out" throughout the whole course of the operations—not one; a fact which redounds highly to the credit of the force. If therefore the strictures passed by THE LANCET refer principally to the Regular Reserve—and it looks like it—it affords much food for reflection for the authorities, and is something to be digested by the conscriptionists, who want the whole nation turned into an armed camp.

Why, may we ask, did our contemporary, "having nothing definite to go upon," only take "the trouble to inquire into the case of at least one Aldershot corps." The war establishment of a division shows no less than 12 infantry battalions as comprising it, yet our contemporary is content to select *one* regiment to test the correctness of our correspondent's statement, and that a regiment famous for its good marching capabilities. Our contemporary by extending its inquiries could have arrived at the names of the units which supplied the casualties and could have published the names if it chose. We may also ask the *United Service Gazette* why a regimental reference was thought sufficient? Where a medical question was at stake inquiry was indicated rather amongst the officers of the Royal Army Medical Corps, whose daily duty it was to pick up the men who fell out on the line of march, and to see that they were carried in the ambulance wagons, and whose arduous task it was also to see by the light of a candle the long stream of weary men who reported "footsore" or "sick" on arrival in camp.

Our contemporary quotes extracts from Mr. Robert Blatchford's views on the Special Reserve, which force, it states, "he treats with a greater sense of justice than THE LANCET." Major-General J. M. Grierson, C.V.O., C.B., C.M.G., is also quoted as having said to Mr. Blatchford, "*and certainly behind the brigades I saw there was not a single straggler, nor did I see one man in the ambulance.*" Is this a denial that there were any men in the ambulances? It is quite probable that there was not a single straggler left behind any brigade, for they were all picked up and put in the ambulance wagons, which we are informed were full to overflowing on the first few days of the week.

The *United Service Gazette* goes on to say:—

The inexperienced correspondent of THE LANCET who appears to have grasped hastily at his facts and lacked the knowledge to sort and arrange them in that orderly manner which befits the matter published in such an authoritative organ of the medical profession. Indeed, after reading the pessimistic and jaundiced views of this sapient contributor to our best known medical journal it is heartening to turn to Mr. Blatchford's cheery pendant to his friendly criticism of the lads of the Special Reserve.

We recognise the politeness of this reference to THE LANCET, but exactly because we feel our responsibilities we take care not to publish the views of inexperienced persons. Our experienced Special Correspondent might well agree with what Mr. Blatchford has said (as quoted by the *United Service Gazette*): "Speaking only of what I have seen I should say that the Special Reserve have done as well as could be expected."

The *United Service Gazette* sums up the case against THE LANCET as follows:—

Here there are two strong pieces of incontrovertible evidence—that furnished by the Royal Irish Fusiliers and that supplied by Mr. Robert Blatchford—to rebut the misleading, not to say reckless, criticism passed on the Special Reserve by THE LANCET, and as that journal has no axe to grind in disparaging voluntary service in order to exalt conscription, we hope its editor will, in common fairness to the Special Reserve, go further into the matter than what, on the surface, he already appears to have done.

We remain impenitent, and satisfied with the thoughtful words of our much-abused correspondent. We hold no brief for conscription, and no one who had read our pages in the least carefully could possibly suggest that we wished to disparage voluntary service. To report accurately upon any medical matter arising out of the army manœuvres is clearly our duty, and the principle of voluntary service is not damaged by such accuracy, but supported.

HOSPITALS AND TAXATION.

IN a review of the annual report of King Edward's Hospital Fund in THE LANCET of Oct. 1st reference was made to the necessary retention of the heading "rates and taxes" among the items of expenditure appearing in hospital accounts, with the suggestion that in consideration of their services to the State hospitals might be freed altogether from contributions to the Imperial revenue. Before proceeding to discuss the privileges already enjoyed by hospitals in this respect, which admittedly are considerable, it may fairly be said that a strong case might also be made out in respect of local taxation, as to which hospitals are in the same position as private individuals or commercial enterprises, unless they enjoy exemption of a special kind under the provisions of a local Act of Parliament affecting them. The debt of the locality to the hospital within its borders is certainly not less than that of the State, for if the good work done in healing the sick and injured and in promoting the progress of medical science tends to the benefit of the nation at large, it even more directly lessens the demand for local taxation by keeping "off the rates" persons who owing to temporary or permanent disablement would otherwise have to seek the assistance of the guardians of the poor. The guardians, moreover, in many localities where their own accommodation is insufficient for serious cases in need of medical or surgical aid, have to entrust those under their charge to voluntary hospitals, and if a payment or contribution is made in return for this benefit the question of its adequacy would have to be considered before pleading it as a defence to a claim for the remission at any rate of the poor-rate. The effects resulting from the work of the hospitals have, however, not been confined to the relief of the poor-rate. The education authority and the sanitary authority, to mention two of the most important branches of local administration, would find their expenses heavier in many places if the voluntary hospitals did not indirectly contribute to lighten them by giving medical aid to poor parents by taking a prominent part in the diffusion of higher ideals in matters pertaining to the health of children and in a variety of other ways.

We pass, however, to the survey of the position of the hospitals with regard to taxation by the Government. In this respect they enjoy already, as has been said above, exemptions, but it must be recollected that these remissions are not given without substantial consideration in the form of public service freely rendered to the community. The Finance Act (1910) contains special provisions affecting charitable institutions, prompted by the same spirit which actuated previous statutory recognition of the great work done in the United Kingdom by voluntary charity, and the new provisions referred to follow lines already laid down. It will be remembered that the Legislature concerns itself with charity and charitable institutions generally, and that hospitals for the sick are never named as such, but are accorded privileges in so far as they are charitable institutions. With regard to income-tax, hospitals received important recognition under the Act which in 1842 granted to Her late Majesty "duties on profits arising from property, professions, trades, and offices." Subject to provisions as to formalities necessary to prevent abuses, and to conditions securing the strictly charitable purposes for which the premises and incomes affected are to be employed, hospitals are exempt from taxation in respect of their buildings and premises and of repairs to these; in respect of rents and profits of lands; in respect of their stock or dividends and annual profits: while provision is made specially in another Act, the Charitable Trusts Act, 1855, for the mode of exemption from tax of their incomes arising from stock in the Funds. Part IV. of the Finance Act, 1910, is to be construed with the Income Tax Act, 1842, referred to above, and these two Acts and the Income Tax Act, 1853, are to be referred to as "The Income Tax Acts," the exemption described being thus not affected. Hospitals are exempt from Inhabited House Duty under the House Tax Act, 1808, being included in a provision to that effect relating to "any hospital, charity school, or house provided for the reception or relief of poor persons." Cases have been brought forward to decide the effect of the reception of paying patients upon this exemption, and the result of the judgments given appears to be that the contributions of

paying patients do not necessarily deprive the hospital of its right to avoid Inhabited House Duty. The cases upon this subject, and a useful summary of the law in general as to hospitals and taxation, will be found in A. T. Murray's "Law of Hospitals."

Hospitals then in existence were exempted from land tax by the Land Tax Act, 1797, as to sites actually occupied by them. We need not recite the various duties payable upon land under the Finance Act. 1910, but quote Section 37 (1), which states the exemption affecting hospitals:—

> No reversion duty or undeveloped land duty under this part of this Act shall be charged in respect of land or any interest in land held by or on behalf of any governing body constituted for charitable purposes while the land is occupied and used by such a body for the purposes of that body, and increment duty shall not be collected on any periodical occasion in respect of the fee simple of or any interest in any land held for the purposes of such a body, whether it is occupied or used by that body or not, without prejudice, however, to the collection of the duty on any other occasion.

The expression "governing body constituted for charitable purposes" includes any person or body of persons who have the right of holding, or any power of government of or management over any property appropriated for charitable purposes (including property appropriated for the purpose of any of the naval or military forces of the Crown), and includes any "corporation sole" and all universities, colleges, schools, and other institutions for the promotion of literature, science, or art. It is to be observed that, except with regard to the "periodical occasions," this section affects only the land occupied by the governing body for its own purposes, and that therefore the exemption granted does not apply, for example, to land let by it to tenants. Its land thus occupied is exempt from such increment duty as otherwise would be levied on the "periodical occasions" referred to, but "without prejudice to the collection of the duty on any other occasion"—i.e., on the land being sold increment duty will be payable on the basis of the increment since 1909, if such duty has not been paid meanwhile.

Corporate bodies whose property, owing to their continuous existence, would otherwise contribute nothing to the revenue to correspond with the probate, legacy, and succession duties accruing where individual owners are concerned, are taxed by the Customs and Inland Revenue, Act, 1885, at the rate of 5 per cent. upon the annual value, income, or profits of their possessions, but there is an exemption from this "corporation duty" which covers the case of hospitals by excluding income or profits "applied for any charitable purpose."

So substantial a portion of the funds of hospitals is derived from the gifts of wealthy persons of mature age or from bequests taking effect when they die, that the various "death duties" affect them considerably. Legacy or succession duty is charged at the highest rate, 10 per cent., upon all gifts made to hospitals which would be liable to such duty if the property passed to individuals, unless, of course, the testator provides that the gift shall be "free of duty" and his estate is sufficient to render it such. It will be remembered that under the Finance Act, 1910, the amount of the estate passing at death is to be calculated so as to include property given away by the owner within three years of his decease, the period of three years being substituted for the one-year limit previously provided in this respect. From this change, however, gifts made for public or charitable purposes are (*inter alia*) excepted, and for these the one-year rule remains in force. This is a concession of advantage to the donees affected, as no doubt it should tend to encourage donations during the life-time of the giver, or at all events should diminish the discouragement introduced by the three-years rule. A donor who knew that his estate would cease at the end of a year to be liable to duty in respect of the property forming the subject of the gift at the end of one year, would presumably give more freely, than if this liability were extended to three years. Such liability, moreover, as may directly affect the property given will end after a year instead of lasting for three years.

It will be seen from the above that on the whole hospitals, in common with other charitable institutions and foundations of public benefit, have had their claims to special consideration recognised to a very large extent. If they "ask for more," both in respect of such loss as they may suffer through the payment of heavy legacy duties, and through their liability as ratepayers, they have more arguments than one in support of their claim for extended privileges. To put these briefly, their expenses are vastly heavier than they once were, and must continue to increase, representing, however, vastly greater benefits conferred by them on their patients owing to improved but more costly methods in medicine and surgery. These improved methods are largely due to discoveries made in the hospitals themselves. The burden of rates increases annually. The increasing burden of modern taxation tends to diminish the revenues of hospitals by checking the flow of gifts from the living and of bequests from the dead.

SANITATION IN INDIA.

(*Continued from p. 1144.*)

Hospitals and Dispensaries.

SOME idea of the scale on which medical work is carried on in the province of Bengal may be gathered from the fact that the total number of patients treated during 1909 amounted to 3,437,053; most of these were, of course, outdoor attendances, but the indoor patients numbered 69,130, of whom 51,860 were either cured or relieved, and 7230 died. The Medical College Hospital in Calcutta had nearly a thousand fewer in-patients than in 1908, some of the wards having been closed for quadrennial repairs. Small-pox and plague were rife in the city, but malaria and cholera were not so prevalent. A regrettable occurrence was the death of three children in the Presidency hospital from cholera, they being under treatment for other complaints; they are said to have partaken of food given by the nurses, among whom there was at the time a virulent outbreak of the disease. Beri beri and epidemic dropsy caused relatively numerous admissions, and an inquiry is now being conducted into the prevalence of these diseases by Captain E. D. W. Greig, I.M.S. The officiating Inspector-General of Civil Hospitals, Lieutenant-Colonel F. J. Drury, I.M.S., notes that nursing is still the weak point in most hospitals for want of funds; the whole question of nursing is now under consideration. In the enormous task of fighting malaria much good has been done by deputing civil hospital assistants to malarious districts to distribute medical aid; 19 were detailed for this duty, and their work was much appreciated. Over a million and a half packets (10 grains) and tablets (3½ grains) of quinine were sold to the people, who now much appreciate the value of the drug as a prophylactic. In the district of Champaran, bordering on Nepaul, the cases of goitre (25,411) amounted to nearly one-fifth of the total number of patients treated. The surgical operations performed numbered 174,127; death resulted in 575 cases, but 162,928 are returned as cured.

In the province of Eastern Bengal and Assam the number of patients treated in dispensaries reached a total of 3,466,068, of whom 25,755 were indoor cases; 19,082 of these were cured or relieved and 2094 died. Malarial fevers were the most frequent cause of illness, and next to them intestinal worms. In the Mymensingh district occurred 21,193 cases of goitre, about one-third of the total for the whole province.

In Upper and Lower Burma the total number of cases treated in dispensaries was 1,241,503, of whom 53,488 were indoor patients; 44,926 were cured or relieved, and 3909 died. The important event of the year was the opening of the new General Hospital at Rangoon, which will accommodate 518 patients. Colonel H. St. Clare Carruthers, I.M.S., officiating Inspector-General of Hospitals, states that this is an up-to-date hospital, with new operation theatre and appliances for the aseptic treatment of wounds, &c. There were 1032 major operations during the year; the mortality was only 7·2 per cent., compared with 10·6 in 1908; moreover, there were 50 more abdominal operations than in the previous year. A scheme for training ten Burmese and Karen women in sick nursing has been prepared, and is only awaiting provision of the necessary funds.

In the Central Provinces and Berar the total cases treated in dispensaries amounted to 1,779,060, the indoor cases numbering 13,776. There was a decrease in malarial fever, but this is ascribed to the presence of plague, at which time there is a disinclination on the part of those suffering from fever to attend the dispensaries. Cholera was also prevalent during the year.

In the recently constituted North-West Frontier province a considerable increase in the number treated of

both indoor and outdoor patients is recorded, and viewed with satisfaction by the Chief Commissioner and by Lieutenant-Colonel G. W. P. Dennys, I.M.S., the Administrative Medical Officer, as it shows that the people are now appreciating the medical assistance provided. The year has not been an unhealthy one. Great improvements have been made in the Egerton Hospital at Peshawar, and new hospitals and dispensaries have been opened at various places. There is no doubt that the humanising and civilising effects of medical and surgical treatment are making themselves felt among the wild population of this borderland. A great increase took place in the number of operations performed, especially in those for cataract and vesical calculus, the Bannu and Peshawar Mission Hospitals and the Egerton Hospital at Peshawar being especially mentioned. Complaint is made of the difficulty in getting men of the assistant surgeon and hospital assistant classes to serve in the province. This part of the country does not itself produce men of this sort, and they will not come from other parts of India to "serve in a province like this, where the amenities of life are so few, where the danger to life and property is so great, and in which they are to all intents and purposes exiles from their homes, and serving among people with whom they have little in common." It is to be hoped that this statement by the Administrative Medical Officer will meet with attention from the provincial and central authorities. The total number of cases treated was 699,796, of whom 11,304 were indoor patients; 9863 of these were cured or relieved, and 323 died. Malarial fevers caused the greatest number of admissions, but these were much fewer than in the previous year. In spite of heavy rainfall 1909 was not a bad fever year; also there was very little cholera.

In the United Provinces the total number of patients treated in hospitals and dispensaries was 4,936,599; of these, 69,741 were indoor patients; 56,241 were cured or relieved, and 3452 died. Although the malaria outbreak of 1908 had been the most severe since 1879, an even larger number of patients—no less than 1,492,487—were treated for these fevers in 1909. The greatest numbers treated for fever were at Gonda (136,942) and Lucknow (110,032). Colonel C. C. Manifold, I.M.S., Inspector-General of Hospitals, informs us that an inquiry was instituted at Cawnpore into the excessive mortality of infants under one year. It was found to be largely due to tetanus or septic disease at birth, the cut surface of the cord being smeared with all sorts of deleterious matter, often mixed with mould containing the tetanus bacillus. Deaths from so-called convulsions are often due to tetanus.

From the report on the Punjab dispensaries by Colonel T. E. L. Bate, I.M.S., Inspector-General of Hospitals, it appears that the total number of patients treated reached 4,511,751. Of these, 77,935 were in-patients, 67,938 were either cured or relieved, and 2492 died. A considerable decline took place in the malarial cases, compared with the previous years; also a reduction in dysentery and diarrhœa. The province was free from epidemic disease during 1909.

Jails.

The administration report on the Bombay Jail Department for 1909 by Lieutenant-Colonel J. Jackson, I.M.S., Inspector-General, deals with a total number of 23,194 prisoners, the daily average strength having been 8984. The death-rate during the year was 17·5 per 1000, practically the same as in 1908, and the lowest recorded for the last 30 years, except in 1905, when it was 17·1. Of the 157 prisoners who died, 4 were admitted in a dying condition and 38 in bad health; the chief causes of death were pneumonia (3·2), tubercle, and dysentery (2·0 per 1000). Many, if not most, Indian prisons are in a chronic state of overcrowding, which leads to difficulties in maintaining a sanitary condition of the prisoners. At Dharwar there were 3 cases of plague, with two deaths. Although the prison was overcrowded no spread occurred, all the prisoners having been inoculated. Rats had been dying in the prison for some time, and the disease was prevalent in the neighbouring village of Saidapur. The common prison at Bombay had 17 deaths, giving the high death-rate of 42·4 per 1000, but 7 were already ill when admitted. "The Bombay habitual is a syphilitic, malaria-sodden, debauched person. Every healthy prisoner is sent to the Deccan gang, and the residue are prisoners of poor physique." At the House of Correction at Bombay there were 6 deaths, 4 occurring in men who were in bad health on admission to prison. At Ahmedabad 8 deaths occurred from dysentery and diarrhœa. It is stated that special care is being devoted to the preparation of food and the regular examination of any prisoner losing weight. Cerebro-spinal meningitis caused 17 admissions and 5 deaths at the Central Prison, Hyderabad (Sind). At the Yerravda Central Prison, the largest in the Presidency, with an average population of 1515, the death-rate was only 14·5 per 1000, which is a very satisfactory figure. Four out of the 20 deaths that occurred were due to senile decay. Various improvements in dieting were carried out during the year, extra rations were issued to weakly prisoners and convalescents, extra warm clothing given when necessary; and lastly, as a result of prison detention it was found that of the total number of prisoners who were discharged during the year (16,582) no less than 54·9 per cent. gained weight, and 28·8 per cent. remained stationary.

In the province of Eastern Bengal and Assam the total prison population was 45,182, the daily average being 7893. 226 deaths occurred, being in a ratio of 28·63 per 1000. Cholera caused four deaths, distributed sporadically over four separate outbreaks. Dysentery caused 57 deaths out of 1357 cases. Major B. J. Singh, I.M.S., Inspector-General of Prisons, is of opinion that its prevalence is connected with the condition of pyorrhœa alveolaris. In two jails where dysentery was prevalent he found a large majority of the prisoners to be suffering from this condition of the mouth; while at two other jails, where all the men's teeth and gums were taken care of, and in a healthy condition, there were hardly any cases of dysentery. Quinine was issued as a malaria prophylactic with very good results. Dysentery was the cause of the highest death-rate, 8·3 per 1000; and pneumonia of the next highest, 4·5 per 1000. Of the 12,841 prisoners discharged during the year, 56·6 per cent. had gained, and 26 per cent. had neither lost nor gained, weight since admission.

In the United Provinces of Agra and Oudh, according to the report of Lieutenant-Colonel C. Mactaggart, I.M.S., Inspector-General, the average number of prisoners during the year was 26,075, and the death-rate 23·7 per 1000. This was nearly as high a rate as in the very feverish year 1908; the malarial epidemic, indeed, continued during the early months of 1909. In almost every jail a large number of prisoners were admitted with enlarged spleens and other signs of malarial cachexia. Bareilly Central Prison and District Jail, Lucknow Central Prison, and Saharanpur Jail, all had high death-rates (over 40 per 1000). At Lucknow Central Prison cholera broke out, necessitating the removal of over 800 convicts into camp at the end of July, while the rains were very heavy. Cholera caused 20 deaths, dysentery 20, and diarrhœa 9; the total mortality was 44·9 per 1000. There were also 3 cases of cholera and 2 deaths at the Lucknow District Jail. In neither of these prisons was there any infection of the water or food-supply, and it was thought to have been spread through flies. The Central Prison and the District Jail at Bareilly had the high death-rates of 40 and 42·7 per 1000 respectively; they both receive prisoners from the highly malarious Terai districts, most of them having enlarged spleens. Saharanpur had the highest death-rate of 43·2 per 1000, due to pneumonia, dysentery, and malaria. Malaria was prevalent throughout the provinces, and quinine was administered prophylactically in 15-grain doses to nearly all prisoners from August to October, as in the Punjab jails, but Lieutenant-Colonel Mactaggart admits that he is disappointed in regard to its prophylactic value.

In Lieutenant-Colonel G. F. W. Braide's report on the Punjab jails attention is drawn to the unenviable notoriety of the Ferozepore district, which heads the list in regard to prevalence of crime; this is considered to be mainly the result of the spread of drinking habits amongst the flourishing peasantry. "It is the same all the world over, alcohol and crime walk ever hand in hand; and it is sad to contemplate the tainting of the sober, robust, hard-working Punjabi with this social evil." The figures for malaria are remarkable; from an average convict population of 10,514, there were only 1525 admissions to hospital and two deaths from malarial fever, being in a ratio of 145 and 0·19 per 1000 respectively. Both deaths occurred at Gurdaspur jail, and there seems to have been an uncertainty whether they were really due to malaria or not. Of the cases, only 408 were observed during the four autumn months when the prisoners were

under the prophylactic influence of quinine. During this period some remarkable returns were made; for instance, in the Lahore Central, Rawal Pindi, Gujrat, and Ludhiana jails, as few as three admissions and under were shown. Following, as it did, on the good results obtained in 1908, Lieutenant-Colonel Braide reiterates his conviction that this "complete immunity is obtained by quinine prophylaxis. If the prison population were not a floating one, if an admission dose throughout the year were not prohibitive on account of cost, and if there were no slackness of administration, there would be no malaria in Punjab jails." In 1908, an excessively malarious year, the admission-rate from fever was only 164 per 1000, the mean-rate for 1902–06 having been 365. Colonel Braide's method that proved so signally successful was, during August to November, to give every prisoner on admission 10 grains, and once a week afterwards 15 grains, of quinine.

The medical history of the jails in Burma for 1909 has been very satisfactory; though not quite so favourable as in the three previous years, both admission- and death-rates have been lower than at any preceding period. At Mandalay the health was exceptionally good until July, when an outbreak of 37 cases of cholera occurred with 28 deaths; the disease was considered to have been introduced and propagated by flies. Dysentery caused 257 admissions and 23 deaths, and tuberculous disease 121 admissions and 60 deaths, almost all in the jails of Lower Burma; in other respects the health of the prisoners was good.

Lieutenant-Colonel W. B. Lane's report on the jails of the Central Provinces is short and pithy. The total jail population amounted to 16,409, the average strength being 3849, and the death-rate was 15·59 per 1000. At Raipur and Jubbulpore numerous cases of dysentery and diarrhœa were noticed to occur in prisoners soon after their admission to prison. Lieutenant-Colonel Lane feels more and more sure that this is due to "unaccustomed plenty." Major C. H. Bensley also believes that it is often the result of overfeeding. "The general public in India consider the prisoner too well fed, and prisoners on release preach about the good and regular diet" (p. 7). Accordingly penal diet has been largely prescribed, with or without solitary confinement.

The North-West Frontier province had a total jail population of 9133, the average number present being 1218; the death-rate was 22·99 per 1000, dysentery and pneumonia being the most fatal diseases. Malaria was not very prevalent, but considering that all prisoners received prophylactic quinine treatment Lieutenant-Colonel Dennys considers the results to be disappointing. He doubts if all the cases really were malaria, suggesting that some were due to sand-fly (phlebotomus) fever. A further series of experiments on quinine prophylaxis was carried out at Peshawar and Dera Ismail Khan jails; at each jail three gangs were formed of equal numbers of prisoners, A gang receiving no quinine, B gang receiving 5 grains every morning, and C gang 15 grains every fifth and sixth day. This was carried out from July 1st to Nov. 30th. At Peshawar each gang consisted of 30 men; 11 in A gang, 6 in B gang, and 1 in C gang were admitted for malaria. At Dera Ismail Khan the gangs were of 47 men in each, and the malarial admissions in A, B, and C were respectively 26, 7, and 2. Another gang, X, "consisting of prisoners not included in the other three gangs who were in jail on July 1st and who were admitted after that date," received 15 grains every fifth and sixth day with C gang; they had 16 cases of fever. In each experiment the administration of 15 grains every fifth and sixth day gave the best results, whereas in 1908 5 grains every day had appeared to be the best treatment. Typhus fever broke out in Peshawar jail, causing 21 admissions and 5 deaths. The patients were treated in tents and bed bugs destroyed.

(To be concluded.)

"LUSUS," a book of verse and prose, by Mr. Christopher Stone, will be sold on behalf of the Prince Francis of Teck Memorial Fund for the endowment of the Middlesex Hospital. Copies, price 5*s.* each (postage 4*d.* extra), may be obtained from Mrs. Christopher Stone, 177, St. James's Court, Buckingham Gate; from Mr. B. H. Blackwell, the publisher, 51, Broad-street, Oxford; or from Messrs. J. and E. Bumpus, Messrs. Truslove and Hanson, and Messrs. Hatchards, who have kindly undertaken to sell copies for the Fund.

PRISONS IN EGYPT.[1]

As a help towards public security and morality the Egyptian Government now provides three convict prisons, ten central prisons in the chief towns, and nearly a hundred local gaols in the country districts. During the year, 93,165 prisoners were admitted, mostly of the male sex, and the daily average of persons in confinement was 13,420. More than three-quarters of the individuals sentenced to fine or imprisonment paid the amount, although the fines averaged 11*s.* This is a large sum in a country where the labourer does not, as a rule, gain more than 10*s.* a week, and it shows that the friends of the fellah possess money concealed for such an emergency, and also that imprisonment is considered rather more deterrent than it once was. The report is illustrated by several tables, from one of which we see that 55 per cent. of the sentenced prisoners were agricultural labourers, while artisans contributed 17, domestic servants 3, and Government officials no less than 7 per cent. Egypt is not exceptional in finding that penal servitude has no terror for the habitual offender, "who is usually back in prison again after a few weeks or months." An attempt to deal with these "in-and-out" prisoners is being made by the establishment of an Adult Reformatory, by which it is calculated that the expenditure need not be increased and some good may be achieved. Whipping, under the order of the courts, was administered to 3375 boys during the year, and 314 boys and 32 girls were admitted to the Juvenile Reformatory, more than half of whom were sentenced under the Waifs and Strays Law. It is satisfactory to note that of 117 boys released from this reformatory in 1907, 63 per cent. are reported by their employers to be doing well, though 13 per cent. have been reconvicted and 24 per cent. have been lost sight of.

Since 1901 certain prisoners have been allowed by a new law to elect to work out their sentence by forced labour, instead of going to prison, and this has the double advantage of reducing the overcrowded state of the prisons and of keeping minor delinquents from the contamination of prison life. The figures under this heading for 1909 show that 13,842 men elected to labour rather than go to prison, 407 of them failed to report themselves, and 737 others absconded before their allotted task was completed, but the remainder faithfully finished their appointed tale of work. Corporal and minor punishments considerably exceeded in figures those of the preceding year, the offences requiring these can partly be traced to the wave of unrest and discontent with constituted authority which has lately swept over Egypt.

Dr. R. G. Kirton, the chief medical officer of the department, in his report draws attention, not for the first time, to the congested state of all the prisons throughout the year, and attributes the comparative freedom from epidemics to the high standard of cleanliness and to the zeal of the Egyptian medical staff. He adds: "This overcrowding in the prisons makes them peculiarly liable to widespread infection. The tinder is present and may be lit at any moment. Epidemics in the prisons not only disorganise prison work and that of the judicial and public authorities, but are also a grave danger to the general public health." He has fully analysed the vital statistics of the year, and shows that the mortality per 1000 has been reduced from 13·6 in 1908 to 12·4 last year. More than half of the deaths occurred between the ages of 15 and 30 years. Infectious diseases were responsible for 15 deaths—namely, 7 from typhus, 4 from cerebro-spinal fever, 2 from relapsing fever, and 1 each from small-pox and erysipelas. Twenty-three deaths were due to phthisis, but the mortality per 1000 from this cause has been reduced to 1·7, from 4·1 in the year 1905. The seven deaths from typhus occurred at Tanta, which is one of the most overcrowded prisons and where there were 46 cases of what used to be called "jail fever." The total number of typhus cases which occurred in all the prisons was 64. Of relapsing fever there were 95 cases reported, of which 24 occurred in a batch of boys newly admitted from an institution. The decrease of late years in typhus and relapsing fevers is undoubtedly due to the greater cleanliness of the provincial prisons and to the war waged against bugs and lice. Twenty cases of leprosy were reported, and 927 cases of diarrhœa and dysentery were treated, a

[1] Report for the year 1909 of the Egyptian Prisons Department, Cairo. 1910. Pp. 90.

number which would doubtless be decreased if overcrowding could be prevented.

The net profit of the year on the prison industries works out at more than £16,000, being an improvement on the preceding year, and great credit is due to those who have to find regular occupations for 13,000 prisoners, drawn from a class of non-workers. The distribution of the boys in the reformatory in different trades comprised printers, book-binders, carpenters, shoemakers, tailors, tin-smiths, blacksmiths and fitters, farm workers, gardeners, and musicians, while the girls were taught sewing, laundry work, and cooking. The general improvement in Egyptian prisons of late years reflects great credit on Coles Pasha, C.M.G., the Director-General, who has had many years' experience of police and prison administration both in India and in Egypt. It is only a quarter of a century ago that the practice of the Egyptian authorities was to arrest not only everyone who might have been implicated in a crime, but also a number of their relatives as well as all the witnesses, whether they were on the side of the prosecution or of the defence, and when once in prison no distinction was made between those who were awaiting trial and the witnesses, who were imprisoned because it was more convenient to keep them in case they were wanted, than to set them at liberty.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8001 births and 4801 deaths were registered during the week ending Nov. 12th. The annual rate of mortality in these towns, which had been equal to 13·0 and 13·1 per 1000 in the two preceding weeks, rose to 14·8 in the week under notice. During the first six weeks of the current quarter the death-rate in these towns averaged 13·3 per 1000. In London the death-rate during the same period, calculated on the probably over-estimated population, was also equal to 13·3 per 1000. The 4801 deaths from all causes registered in the 77 towns last week showed an increase of 551 upon the number in the previous week, and included 392 which were referred to the principal epidemic diseases, against 504, 425, and 361 in the three preceding weeks; of these 392 deaths, 136 resulted from measles, 110 from diarrhœa, 54 from diphtheria, 37 from whooping-cough, 32 from enteric fever, and 23 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·2 per 1000, against 1·6, 1·3, and 1·1 in the three preceding weeks. No death from any of these diseases was registered last week in Leicester, Croydon, South Shields, Hornsey, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·2 in Brighton, 4·1 in Rhondda, 4·5 in West Hartlepool, 4·9 in Middlesbrough, and 6·5 in Tynemouth. The fatal cases of measles in the 77 towns, which had been 75, 107, and 101 in the three preceding weeks, further rose to 136 last week, and exceeded the number in any week since the beginning of June; they caused the highest annual rates, 1·9 in West Hartlepool, 3·2 in Brighton, and 5·5 in Tynemouth. The deaths attributed to diarrhœa, which had declined in the ten preceding weeks from 527 to 123, further fell last week to 110, and were proportionately most numerous in Rochdale, Burnley, Rhondda, and West Hartlepool. The deaths referred to diphtheria showed a further increase of 8 upon the numbers in recent weeks, and included 15 in London and West Ham, 4 in Bradford and in Newcastle-on-Tyne, and 3 in Norwich. The 37 fatal cases of whooping-cough exceeded by 5 the low number in the previous week; 7 were registered in London and 3 both in Bristol and in Liverpool. The deaths referred to enteric fever, which had been 30 and 29 in the two previous weeks, rose last week to 32, of which 12 occurred in London and its suburban districts, 3 in Portsmouth, and 2 both in Walsall and in Rhondda. The 23 fatal cases of scarlet fever showed a decline of 7 from the number in the previous week, but included 6 in Liverpool and 3 in Leeds. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily increased in the 12 preceding weeks from 1428 to 1856, had further risen to 1882 on Saturday last; 239 new cases of this disease were admitted to these hospitals during last week, against 221 and 188 in the two previous weeks. The 1476 deaths from all causes in London last week included 319 which were referred to pneumonia and other diseases of the respiratory system, against 194, 234, and 246 in the three preceding weeks, and exceeded by 36 the corrected average number in the corresponding week of the five years 1905–09. The causes of 40, or 0·8 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Sheffield, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Nottingham, and in 49 other smaller towns; the 40 uncertified causes of death in the 77 towns last week included 7 in Birmingham, 5 in Liverpool, and 4 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 784 births and 484 deaths were registered during the week ending Nov. 12th. The annual rate of mortality in these towns, which had been equal to 12·7 and 13·6 per 1000 in the two preceding weeks, declined again to 13·3 in the week under notice. During the first six weeks of the current quarter the death-rate in these eight towns averaged 13·3 per 1000, and corresponded with the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 8·4 and 10·2 in Perth and Leith, to 14·9 in Greenock, and 15·3 in Dundee. The 484 deaths from all causes in the eight towns last week showed a decline of 8 from the number in the previous week, and included 47 which were referred to the principal epidemic diseases, against 48 and 56 in the two preceding weeks; of these 47 deaths, 17 resulted from diarrhœa, 11 from diphtheria, 7 from scarlet fever, 7 from whooping-cough, 4 from "fever," and 1 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·3 per 1000, and slightly exceeded the rate from the same diseases in the 77 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had declined in the six preceding weeks from 51 to 23, further fell last week to 17; they included 6 in Glasgow, 4 in Dundee, and 2 both in Edinburgh and in Greenock. The 11 fatal cases of diphtheria showed a decline of 5 from the high number in the previous week, but included 6 in Glasgow and 3 in Dundee. Of the 7 deaths from scarlet fever, 5 occurred in Glasgow and 2 in Dundee; and the 7 fatal cases of whooping-cough (corresponding with the number in the previous week), included 4 in Glasgow. The 4 deaths referred to "fever" were all returned in Glasgow; 3 were certified as enteric fever and 1 as cerebro-spinal meningitis. The fatal case of measles occurred in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 72 and 84 in the two preceding weeks, declined to 65 last week, and were 50 below the number in the corresponding week of last year. The causes of 18, or 3·7 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 555 births and 358 deaths were registered during the week ending Nov. 12th. The mean annual rate of mortality in these towns, which had been equal to 17·4, 16·8, and 15·1 per 1000 in the three preceding weeks, rose again to 16·2 in the week under notice. During the first six weeks of the current quarter the annual death-rate in these Irish towns averaged 16·4 per 1000; the mean rate during the same period did not exceed 13·3 in the 77 largest English towns and in the eight principal Scotch towns. The annual death-rate during last week was equal to 17·1 in Dublin, 16·3 in Belfast, 15·8 in Cork, 15·6 in Londonderry, 6·8 in Limerick, and 15·6 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 17·0 per

1000. The 358 deaths from all causes in the 22 town districts last week showed an increase of 14 upon the number in the previous week, and included 27 which were referred to the principal epidemic diseases, against 42, 33, and 28 in the three preceding weeks; these 27 deaths were equal to an annual rate of 1·2 per 1000, and corresponded with the rate from the same diseases last week in the 77 towns, the rate in the eight Scotch towns being 1·3. The 27 deaths from these epidemic diseases in the Irish towns last week included 11 from diarrhœa, 6 from whooping-cough, 5 from diphtheria, 3 from measles, and 1 each from scarlet fever and enteric fever, but not one from small-pox. The deaths attributed to diarrhœa, which had been 20 and 14 in the two preceding weeks, further declined to 11 last week, of which 3 occurred in Dublin, 4 in Belfast, and 2 in Londonderry. Of the 6 fatal cases of whooping-cough 4 were returned in Dublin and 2 in Wexford; and the 5 deaths from diphtheria included 2 in Dublin and 2 in Dundalk. Two of the 3 fatal cases of measles and the death from scarlet fever occurred in Lurgan. The death referred to enteric fever was registered in Drogheda. The deaths in the 22 towns last week included 88 which were referred to pneumonia and other diseases of the respiratory system, against 66 and 60 in the two preceding weeks. The causes of 17, or 5·1 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·8 per cent., while in the eight Scotch towns it was equal to 3·7 per cent.

THE SERVICES.

Royal Navy Medical Service.

THE following Staff-Surgeons have been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet: William Bernera Macleod, Arthur Harry Hingston Vizard, Harry Spicer, Edward Thomas Philip Eames, John Alexander Lanford Campbell, Harold Paget Jones (dated Nov. 14th, 1910).

The following appointment is notified:—Staff-Surgeon: P. H. M. Star to the *Leander*, additional, for destroyers.

Royal Army Medical Corps.

Captain Robert B. Black, from the Seconded List, is restored to the establishment (dated Nov. 1st, 1910).

The undermentioned Lieutenants are confirmed in their rank:—Frederick R. Laing and John T. Simson.

Colonel T. J. R. Lucas, C.B., principal medical officer of the First (Peshawar) Division, has been transferred as Principal Medical Officer to the Jubbulpore and Jhansi Brigades. Lieutenant-Colonel G. E. Hale, D.S.O., has been posted to the Southern Army in India and appointed to the Fifth (Mhow) Division. Lieutenant-Colonel L. W. Swabey, at present on leave from Aden, has been transferred to the home establishment pending his retirement. Lieutenant-Colonel C. T. Blackwell has been appointed to the Ninth (Secunderabad) Division. Lieutenant-Colonel R. H. Hall, from Colchester, embarks for Bermuda on Nov. 25th, to take up the appointment of Senior Medical Officer recently vacated by Lieutenant-Colonel J. C. Culling on promotion. Lieutenant-Colonel G. G. Adams has been appointed to command the station hospital at Colaba, in succession to Lieutenant-Colonel G. F. Gubbin, whose tour has expired. Major T. B. Beach has embarked for Egypt. An exchange on the roster for foreign service has been approved by the War Office between Major W. W. O. Beveridge, D.S.O., and Major W. G. Beyts. Major H. V. Prynne has arrived home for duty from Gibraltar. Major H. A. Waring, on the expiration of his tour of service in India, has been transferred to the home establishment and has been appointed to the Southern Command. Major G. A. T. Bray has been transferred from the Southern Command to the Eastern Command. Major H. A. L. Howell, on arrival home from Gibraltar, has been appointed Medical Officer in Charge of the Royal Army Clothing Factory at Pimlico. The undermentioned officers, on conclusion of their course of instruction for promotion at the Royal Army Medical College, Grosvenor-road, have been posted as follows: Captain J. P. J. Murphy and Captain A. H. Hayes to Dover; Captain A. McMunn, Captain J. M. H. Conway, Captain W. D. C. Kelly, and Captain A. T. Frost to Dublin; Captain J. McKenzie, Captain M. D. Walker, and Captain H. W. Russell to the London District. Captain G. A. D. Harvey, from Khartoum, has been appointed to the Eastern Command for duty. Captain R. C. Hallowes has arrived home for duty from Egypt. Captain J. H. Gurley has been transferred to the home establishment from Egypt, by exchange. Captain G. A. K. H. Reed has been appointed Specialist in Physical Training to the Aldershot Command. Captain P. H. Henderson has joined at Portsmouth from Ibsley Camp. Captain W. F. Tyndale, C.M.G., has been transferred from Dublin to the Curragh Camp. Captain J. C. G. Carmichael, from Fleetwood, has joined for duty at Chester. Lieutenant D. H. C. MacArthur, from the London District, has embarked for a tour of service in India. Lieutenant T. W. Stallybrass has been transferred from Tidworth Park to Hamilton Camp.

Royal Army Medical Corps School of Instruction.

Major Claude K. Morgan, R.A.M.C., to be an Instructor, vice Major C. C. Fleming, D.S.O., who has vacated that appointment (dated Oct. 29th, 1910).

Indian Medical Service.

Lieutenant-Colonel A. L. Duke, administrative medical officer of the North-West Frontier Province, has been appointed under the Foreign Department of the Government of India to be Agency Surgeon of Baluchistan, vice Lieutenant-Colonel J. Sykes, who is proceeding on combined leave in December. Lieutenant-Colonel A. J. Macnab, on return from leave, has been appointed Residency Surgeon, Srinagar, Kashmir, vice Lieutenant-Colonel W. R. Edwards, appointed Administrative Medical Officer, North-West Frontier Province. Lieutenant-Colonel R. H. Castor, Bombay, has received an extension of his leave. Major A. W. R. Cochrane, on completion of a course of special duty at the Central Research Institute, Kasauli, has taken over the duties of Superintendent of the Lunatic Asylums at Agra. Major B. I. Singh, inspector-general of prisons in the Province of Eastern Bengal, has been granted privilege leave for three months. Major E. J. Perry has been selected by the Central Committee for Malarial Fever Investigation for special duty to study the prevalence of malaria in the Jeypur Agency in Northern Madras. Major F. H. Watling has taken over the Medical Charge of the 48th Pioneers at Allahabad. Major J. A. Black, chemical examiner of Bengal, has been selected to officiate as Chemical Examiner of the Punjab Province, vice Lieutenant-Colonel D. Grant. Major S. Hunt has received one year's extension of his leave. The services of Captain J. B. Christian have been placed permanently at the disposal of the Government of Eastern Bengal and Assam. Captain W. W. Jeudwine, district plague medical officer of Gurdaspur, has been granted three months' privilege leave. Captain W. H. Hamilton has been appointed Specialist in Ophthalmology to the Second (Rawal Pindi) Division. Captain S. Whitworth-Jones has received six weeks' extension of his leave home. Captain M. J. Quirke has been mentioned in despatches for "exceptionally good work" done in Somaliland. Captain C. A. Gourlay has been confirmed as Civil Surgeon under the Government of Eastern Bengal and Assam. Captain R. M. Carter, from the Pasteur Institute at Kasauli, has been granted eight months' leave home from India. Captain T. F. Owens has been appointed to officiate as Professor of Chemistry at the Medical College, Calcutta.

Territorial Force.

Royal Army Medical Corps.

2nd South-Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: John Robinson Benson, late Lieutenant, Army Motor Reserve, to be Lieutenant (dated Sept. 16th, 1910).

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., to-day (Friday) at 8 30 P.M., when Sir Rubert Boyce will read a paper (with lantern demonstration) on Yellow Fever in West Africa, and the following papers, which have been approved by the council, will be presented to the society:—(*a*) Autochthonous Oriental Sore in Panama, by Dr. S. T. Darling, chief of the laboratory, Ancon. (*b*) Tropical Diseases in British New Guinea, by Dr. R. Fleming Jones, Samurai.

Correspondence.

"Audi alteram partem."

PLAGUE AMONG EUROPEANS.

To the Editor of THE LANCET.

SIR,—There seems to be a general impression that plague could not possibly become epidemic among Europeans. As this is likely to lead to viewing the spread of plague-infected lower animals over different parts of the country with comparative complacency, I send you the figures which I submitted to the Colonial Office in May of 1901 regarding the plague outbreaks in Cape Town two months before the last case.

Cases of Plague.

Europeans.	Coloured.	Natives.
164	342	133

Cape Town with its suburbs is a comparatively small town. Rats had died a very considerable time before the outbreak, and when the epidemic began there were very few rats to be seen. The close connexion between rat plague and human plague was only accepted in a half-hearted manner until there was a succession of cases in which dead rats were found in the houses, and in one particularly which was badly infected where 105 dead rats were found under the floor and behind the wainscot and panelling. There is also another impression that plague behaves always in the same way, and that because there was a small percentage of pneumonic cases in India and Cape Town, whilst in Sydney until recently there were no pneumonic cases at all, therefore a small percentage of pneumonic cases is a law of the disease. In 1908 on the Gold Coast there were both bubonic and pneumonic cases of plague, and instead of 4 to 8 per cent. of pneumonic cases there was over 50 per cent.

Until England can deal effectively with her influenza epidemics she cannot afford to sit down and not deal vigorously with the plague-infected lower animals in Suffolk in the hopes that nothing may happen. She may be right; on the other hand, she may be wrong. And the wisest course is to treat the rat plague as *the plague*, and bring every available force to bear to get it out of the land.

I am, Sir, yours faithfully,

King's College, Nov. 15th, 1910. W. J. SIMPSON, M.D.

VOLUNTARY AID DETACHMENTS.

To the Editor of THE LANCET.

SIR,—Lieutenant-Colonel A. C. Yate in his communication on the above subject is not fortunate in his comments upon the British Red Cross Society. He says that almost all the members of the voluntary aid detachments raised by the society hold the St. John Ambulance Association certificate. That is true; but he omits to add that until August 8th, 1910, that certificate was, by an existing arrangement now abandoned, the only one available for the purpose. The detachments referred to were for the most part raised before August, 1910, as Lieutenant-Colonel Yate must be aware. Since that date the War Office has recognised a large series of certificates in first aid and among them the certificates of the county councils. It will follow from this that the preponderance of the St. John certificate will be much less conspicuous in the future.

Your correspondent states that the society has undertaken to provide two things—viz., a manual of instruction and an inspecting staff. The manual employed by the society is the "Manual of the Royal Army Medical Corps," which can be obtained for 9*d*. A special manual has been prepared for the society by Mr. Cantlie and is ready for the printers as soon as it has received the sanction of the War Office. The society never undertook to provide an inspecting staff, nor even contemplated such a provision. The organising secretary of the society, Colonel J. Magill, C.B., undertakes to advise as to the formation of detachments in any district and has done a great deal of work under that head.

Your correspondent complains of the "prodigious" number of forms issued by the society. The form dealing with the whole subject under notice is one in number—viz., Form D.

The work of the British Red Cross Society, in raising detachments throughout the country, is proceeding rapidly and with an enthusiasm worthy of so humane and patriotic a movement. For the success of this work the society has to thank many, and above all the medical men of the country, who have so generously given their assistance.

I am, Sir, yours faithfully,

FREDERICK TREVES,
Chairman of the Executive Committee.

Victoria-street, London, S.W., Nov. 10th, 1910.

MEDICAL ETHICS AND MEDICAL ETIQUETTE.

To the Editor of THE LANCET.

SIR,—In a book on the subject of "Medical Etiquette," by Dr. Surbled of Paris, which has just been translated by Dr. W. P. Grant, and for which, by desire of the author, I wrote a brief preface, I find to my great regret that the excellent lectures of my friend Professor Saundby, which he published in 1902 (second edition in 1907), had quite escaped my memory when I referred to the absence of any recent English literature on the subject. Dr. Saundby's book on "Medical Ethics" is an admirable one.

I am, Sir, yours faithfully,

Grosvenor-place, S.W., Nov. 12th, 1910. DYCE DUCKWORTH.

THE FERTILITY OF THE UNFIT.

To the Editor of THE LANCET.

SIR,—Many writers and speakers take an unfavourable, and some an alarmist, view of the prospects of maintaining the vigour of our race. This is illustrated by a discussion at the recent Church Congress. The unfit, we are told, are increasing faster than the fit elements of the population. Mrs. Pinsent of Birmingham is reported to have said that efforts to improve the race by ameliorating the environment are futile. They only serve to perpetuate the evil conditions which they aim at removing. Heredity, it is averred, will always beat environment into a cocked hat. A journalistic placard announces "The Fatal Fertility of the Poor." The birth-rate among mentally defective persons is declared to be high, whilst that of the middle and upper classes is artificially limited. The last statement rests unhappily on a solid basis of statistics and of common experience, and I do not deal with it here.

But statistics on the fertility of the mentally and physically defective portion of the population are not easy to obtain. Those who have watched the working of natural laws have reason for believing that Nature is always trying to improve the breed and to eliminate defects. From a study of pedigrees and long observation of families I am inclined to agree with this view. Such improvement is effected partly by mixing with healthier stocks, partly by sterilising those which are defective below a certain standard. The sterilisation must be looked for, not in one generation only, but in two or three; that is to say, that if the pedigree of a defective person is traced, then either by combining with better strains the succession is maintained and the defect gradually eliminated, or, if the defect is too great or the new stocks are also defective, the progeny dies out in one, two, or three generations. In the words of Dr. F. W. Mott, dealing with the inheritance of a tendency to insanity, "As a rule, there is either a regression to the normal or the stock dies out."

Thus the unfit disappear, and the fit prevail. It will be said these are only general impressions. Yet are they not consistent with the experience of breeders of animals, with the conditions of the struggle for existence, and with a tendency to be traced all through vital phenomena for the survival of the fittest? But it is said that we have altered the conditions in which Nature is working by preserving alive many unfit who would have died, and by so caring for their welfare as to enable them to increase in the community, and that in this manner the efforts of philanthropy and the kindness of modern civilising agencies in reality tend to the deterioration of the race. This is a serious statement, and can only be fully met by facts and statistics which are not as yet available, but to some of which I will allude presently. In the meantime, two considerations may be advanced. In the first place, the sum total of modern efforts to improve the welfare of all classes of the community, by which the unfit are made less unfit and the fit made fitter, should surely tend to help and not to hinder the progress of the race as a whole. Secondly, to enter into more detail, with regard to those who were born

so physically or mentally defective that they would have died in childhood but for the philanthropic care received, a large number of these will remain below the standard of ability to propagate their kind, and others will be so far raised by the care received as to become sound members of the race. The intermediate class, consisting of those unfit who have been enabled by special aid to live and to become parents, will be subject to the conditions already pointed out; there will be "a regression to the normal or the stock dies out" in a very few generations. These are again general impressions and appeals to probability, but so are the statements which they controvert; we need facts. Well, but we are informed that the birth-rate of the mentally defective is high, and the Report of the Royal Commission on the Feeble-minded is freely referred to in support of this statement. I turn to this Report and find, indeed, mention of various instances of weak-minded women who had large families of children. But when the Commissioners come to sum up the matter judicially they state (vol. viii., p. 198), "With one or two exceptions, sifted and precise statements on the subject are wanting." Again, "It is, we feel, a matter of serious regret that more scientific evidence on the birth- and death-rates of the mentally defective is not forthcoming." It is plain, therefore, that the Report furnishes no sufficient ground for the assertion of a higher birth-rate. Dr. Mott's recent Huxley Lecture[1] on the Hereditary Aspects of Nervous and Mental Diseases touches little on the question of fertility. He states, however: "In a number of pedigrees obtained from an imbecile asylum ..... I observe (though the numbers are not sufficient yet to give any precise data) that the families are prolific ..... but there is relatively a larger number of deaths from various diseases, especially tuberculosis." Such pedigrees, traced upwards from offspring, will naturally deal more with the fertile than with the sterile members of the unfit class.

It would help much to the fuller understanding of this question if vital statistics of the feeble-minded and other varieties of the unfit could be compiled upon a broader basis. They must, however, take note of several generations. It would not be enough to show that feeble-minded women had as large or larger families than sound women, for the vitality and power of procreation possessed by these children must be taken into the account. It will probably be found that many die in infancy and childhood. Meantime, until proof is shown of the exceptional power of the unfit to perpetuate their kind I submit that the opposite view holds the field, and that the influence, both of natural laws and of philanthropic effort, is to raise the stock and not to lower it.

I am, Sir, yours faithfully,

Wimpole-street, W. R. HINGSTON FOX.

CONTINUOUS PROCTOCLYSIS.

To the Editor of THE LANCET.

SIR,—The chief difficulty in the management of continuous proctoclysis lies in the maintenance of the temperature of the saline solution at a uniform degree. The possessor of a "thermos" flask is provided with a simple means of overcoming this difficulty. All the additional apparatus necessary are a U-shaped piece of glass tubing with one arm long enough to reach to the bottom of the flask; three or four feet of rubber tubing attached by one end to the glass tube and connected with the catheter by the other; and, lastly, some means of limiting the flow, such as a metal clip on the rubber tube or the introduction of a tap, such as that supplied with the Rotunda douche. The flask is filled with saline solution at a temperature a few degrees above that at which it is desired to administer the injection, and suspended two or three feet above the patient's bed. The fluid is then run off by syphonage and the flow regulated by the tap or clip. The temperature of the solution will remain at practically the same level, while the bottle slowly empties. At the rate usually advised—viz., one drop per second—only 7½ ounces are used per hour, so that a pint thermos flask will contain sufficient solution to last for two hours.

I am, Sir, yours faithfully,

HENRY W. P. YOUNG, M.D., B.C. Cantab.

Norbury, S.W., Nov. 7th, 1910.

[1] THE LANCET, Oct. 8th, 1910, p. 1057.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University of Birmingham: The Walter Myers Travelling Scholarship.

THE Council of the University of Birmingham at its last meeting elected Mr. Cranston Walker, M.B., Ch.B., B.Sc. Birm., to the Walter Myers Travelling Studentship, and Dr. Walker has proceeded to the University of Freiburg in Baden to carry out a research under the direction of Professor L. Aschoff. This scholarship, which is becoming one of the most important in the medical school, is of the value of £150 per annum, and was founded by Mr. George Myers of Edgbaston for the promotion of original research, and in memory of his only son, Dr. Walter Myers, a former student of Mason University College, who died from yellow fever contracted in Brazil while investigating the cause of the disease on behalf of the Liverpool School of Tropical Medicine. The Council of the University also approved the election of Mr. John Dale, M.B., Ch.B., B.Sc. (Public Health) Birm., for a further year, he having held the scholarship for the year 1909–10 and having proved himself a student of exceptional merit. Dr. Dale is returning to Hamburg to continue his research work in public health under the direction of Professor Dunbar.

Research Defence Society.

The first public meeting of this society was held on Nov. 1st in the Midland Institute. The President, Professor Leith, presided over a large audience, and Professor P. F. Frankland, F.R.S., delivered an eloquent lecture on the Life of Pasteur. A vote of thanks to the lecturer was proposed by Canon Carnegie of the Cathedral Church and seconded by Mr. Cary Gilson, M.A., the headmaster of King Edward VI.'s Grammar School. It is intended to hold three or four such public lectures each year.

Hospital Saturday Fund.

The entire collection for the present year up to date amounts to £20,194, which is £505 more than last year. The usual grant of £10,000 for the twentieth year in succession has been made to the various hospitals of the city. Since the inception of the Fund the following amounts have been handed to the hospitals: The General Hospital (including the Jaffray Hospital), £104,064; Queen's Hospital, £57,780; General Dispensary, £31,101; Children's Hospital, £23,952; Birmingham and Midland Eye Hospital, £17,741; and Women's Hospital, £12,142. Smaller amounts have been received by other hospitals.

Nov. 16th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Conferring of Honorary Degrees.

THE University of Liverpool on Nov. 14th, at the hands of the Chancellor (the Earl of Derby), conferred the honorary degree of LL.D. on the Earl of Rosebery, the Earl of Cromer, Viscount Morley of Blackburn, Sir Archibald Geikie, and the Right Hon. John Burns. The scene was a brilliant and animated one, to which the undergraduates contributed a long series of topical songs. Preceding the ceremony the Lord Mayor entertained those named above and other distinguished guests at luncheon in the town-hall, where speeches were delivered. At noon Lord Rosebery unveiled a commemorative tablet to be affixed to the Students' Union, and spoke on "The True Functions of a University Union."

Liverpool Select Vestry: Complimentary Dinner to Mr. William Alexander.

Mr. William Alexander, who has recently resigned the office of visiting surgeon to the Liverpool workhouse hospital after 38 years' service, was entertained at dinner by the members of the select vestry, at the Adelphi Hotel, on Nov. 2nd. Mr. T. D. Laurence, the "father" of the select vestry, proposed the health of Mr. Alexander in a flattering speech, and presented him with an illuminated address. Mr. Alexander, in responding to the toast, thanked his hosts for the address and for the kind manner in which the toast was received by those present. He also thanked the nurses of

the hospital, and wished every success to his successor, Mr. Arthur J. Evans.

Tuberculosis in Milk.

A farmer of Moss Wood farm, Stretton, was fined £1 1s. and £10 costs at the Daresbury petty sessions last week for allowing a cow suffering from tuberculosis of the udder to remain in a shippon along with other cows. The deputy town clerk of Warrington stated that in June last a sample of milk was purchased from a shop in Warrington. When analysed by Professor S. Delépine it was found to contain tubercle bacilli. The medical officer of health visited the defendant's farm and saw a cow which did not appear satisfactory. It was decided to take a sample of the milk, and this was found to contain tubercle bacilli. The defendant was asked to isolate the cow from the rest of the dairy stock, and not to sell any milk from the cow for human consumption. When another visit was paid by one of the health officials to the farm he found the cow in the shippon along with other cows. When this was brought to the defendant's notice he replied that he thought the corporation were not troubling about the cow again, and he put her back in the shippon a fortnight before. The defence submitted was that the defendant had committed a technical offence, which really meant that he had failed to isolate the cow. During the whole of the time from the moment isolation was mentioned the milk from the cow had never been sent out to customers.

Nov. 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Urgent Plague Precautions.

IN view of the serious occurrence of plague in England the Local Government Board of Scotland has issued an order to all local authorities stiffening the regulations with respect to plague issued in 1902.

Edinburgh School Board and the Medical Inspection of School Children.

An account has been published of the scheme of the Edinburgh school board for the medical inspection of school children. The medical staff consists of the head of the department, who is a medical man, two medical assistants, one of whom is a medical woman, and two nurses. Under the scheme the staff carries out regular visitation of the schools, examination of the pupils, and supervision of cases in which the parents are suspected of neglect. The board is proceeding under two statutes—the Education (Scotland) Act, 1908, and the Children Act, 1908. Three periods in the life of the child are taken as the basis of the medical inspection—the time of enrolment, i.e., at the "infant" school stage, at the age of 9, and at the age of 13, while in addition to the routine examination and inspection special cases are dealt with as they are reported by the teachers. The services of the teachers are utilised in measuring and weighing pupils, and in securing and tabulating data for the health returns. The duties of a headmaster especially in this respect are onerous. No powers are given to the board to provide treatment, the duties of the medical officers being to examine the children, report defects to parents, and bring to the notice of the board children suffering from neglect or cruelty at home. As regards neglected children the board intends to make full use of the powers conferred on it. A definite procedure has been outlined in a circular lately issued to headmasters from the office of the board. This is as follows:—

1. *Notice to the board* to be sent by the headmaster, school medical officer, or attendance officer according to the character of the case.
2. *Warning notice to the parent* to be sent out by the board on receipt of a notice as above from headmaster, school doctor, or attendance officer.
3. *Action by the board.*—If after the "warning notice" improvement in the condition of the child is not effected the parent may be summoned to appear before the board. If on the appearance of the parent an explanation is not forthcoming or proves unsatisfactory, the board may report the case to the Procurator Fiscal of the Sheriff Court in order that proceedings may be instituted against the offending parent under Section 12 (1) (b) of the Children Act, 1908, or Section (6) 2 of the Education (Scotland) Act, 1908.

It is stated that already there is a marked improvement in the condition of children, concerning whom reports have been made to the parents, and that considering the home conditions the efforts made to keep the children clean and wholesome in many cases are surprising. The board is now making arrangements to provide food for the underfed children in the schools, and has approved a plan for creating local or district care committees, which, working under a central committee, will supervise the distribution of food. It is hoped that these local care committees will prove repositories and foci of accurate knowledge with regard to the worst cases in each district, and that the scheme as a whole will lead to a very appreciable difference in the hard lives of many children.

Edinburgh Sanitary Society.

At a meeting of the Edinburgh Sanitary Society on Nov. 10th an address was given by Dr. R. W. Philip on Rest and Movement in Tuberculosis. Dr. Philip first spoke on aerotherapy, which was now one of the widely accepted facts of modern therapeutics. His conviction was, that were the vitalising properties of open air truly realised the larger part of disease would cease to be. Granted that a patient was to be treated on open-air principles, was he to be kept at rest or was he to be allowed movement, and if so, to what extent? The older school of opinion favoured almost complete rest, but in his opinion while rest was helpful, and at certain times essential, prolonged treatment by rest gave unsatisfactory results. The patients might seem to improve, might put on weight enormously, but the increase was usually mere fat, while the skin remained pallid and toneless, and the muscles soft and flabby. The practice of treatment by continued rest proceeded from a faulty conception of the disease. The lesion in the lung was a small part of the illness. The gradual descent downwards—or "decline"—was the expression of a systemic or constitutional intoxication. The toxins produced by the tubercle bacillus appeared especially to affect the neuro-muscular apparatus. The toxin was especially a muscle poison leading to muscular dystrophy. This dystrophy not only affected the muscles of the trunk and extremities but likewise the muscles of the heart, blood-vessels, and other viscera. With such a condition of the muscles the indication was mainly rest, but when the amount of toxin was less the dystrophic muscles tended to recover physiologically if treated by natural movement. Dr. Philip outlined the scheme of physical treatment practised in the Royal Victoria Hospital, which was found to be all that was needed for the majority of patients.

Resignation of the Superintendent of Edinburgh Royal Infirmary.

Colonel W. P. Warburton, C.S.I., superintendent of the Royal Infirmary, Edinburgh, has intimated to the managers of that institution his intention of resigning his post as superintendent. Colonel Warburton entered the Indian Medical Service in 1866 and retired in 1899. During his career in India he held the post of medical officer to the Maharajah of Kaipurthala, and was appointed sanitary commissioner in 1894. Subsequently he held the posts of Inspector-General of Civil Hospitals in the North-West Provinces and Oudh, and of honorary surgeon to the Viceroy of India.

Glasgow Medical Faculty.

A conversazione was held recently by the Royal Faculty of Physicians and Surgeons of Glasgow in the Faculty Hall, St. Vincent-street. About 700 ladies and gentlemen were present, and the gathering was representative of the medical profession in Glasgow and the West of Scotland. A notable feature of the proceedings was the presentation of a mace to the Faculty by Dr. J. Walker Downie. The President, in welcoming the guests, stated that the Faculty had from the very beginning of its career shown a great interest in the medical profession of Glasgow. For the first 250 years of its existence it had practically the sole management of the profession in the city and in a considerable number of neighbouring towns. In these later days they had done a great deal for the profession in a variety of ways. During the past year the late King Edward signified his sovereign pleasure that they should thereafter be called the Royal Faculty of Physicians and Surgeons. They had always been a Royal Faculty in reality, because they were founded over 300 years ago by King James VI. of Scotland, but they never used the title Royal. Whether they were entitled to use it or not he did not know, but at any rate they had now received the right for all time coming to be known as the Royal Faculty.

New Hospital for Skye.

To perpetuate the memory of Dr. MacKinnon of Strath a scheme has been formulated for the building and equipment of a hospital at Broadford, Skye. An ideal site has been secured and plans have been prepared and approved by the local committee. The estimated cost of the building is about £1000. Already a considerable number of subscriptions have been received, the amount in the treasurer's hands being a little over £1600. It has been decided, however, not to commence building operations until a sufficient sum is raised to endow the hospital, and a special appeal for the requisite funds has been issued. The proposed institution will supply a want which has been felt in the east end of the island, as under existing conditions patients have to be conveyed long distances before they can get hospital treatment.

Isolation Hospital for Dumfries and Maxwelltown.

Dr. W. Leslie Mackenzie, of the Local Government Board, performed last week the opening ceremony of the new combination hospital for Dumfries and Maxwelltown for the treatment of infectious diseases at a cost of fully £7000. In declaring the hospital open Dr. Mackenzie spoke in appreciative terms of the vast amount of good work done by voluntary institutions in dealing with infectious disease. Dumfries followed several other towns in providing isolation hospitals for infectious disease, and as these diseases were spread over all classes of the community, it was essentially the duty of the community as a whole to deal with them. He went on to emphasise the need of dealing in a strenuous manner with phthisis, and expressed great satisfaction that, complying with the recommendation of the Local Government Board, local authorities representing over 50 per cent. of the population of Scotland, had already adopted compulsory notification of phthisis.

Dundee Royal Infirmary Staff and Time Gun.

The Dundee Royal Infirmary staff have petitioned the works committee of the Dundee town council on the question of the nearness of the time-gun to the institution. They point out that its firing is injurious to the patients and ask that it should be removed to some other place. The committee, after discussion, agreed that the city engineer should report on the subject at the next meeting and that meantime a less charge of gunpowder should be used.

Nov. 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Action by the Local Government Board against a District Council.

LAST week, in the King's Bench Division, before the Lord Chief Baron, Mr. Justice Gibson, and Mr. Justice Boyd, the Local Government Board made application that a conditional order of *mandamus* issued a few months ago against the Kilmallock rural district council should be made absolute. The order directed the district council to appoint a veterinary surgeon as inspector of dairies and cowsheds to carry out the provisions of a sanitary Order of the Local Government Board. In April, 1908, the council had considered the Order, and refused to take any action, marking the Order "read." The Local Government Board informed the council that the Order was of general application. Dr. Browne, Local Government Board medical inspector, visited the union and reported that in the interest of the public health and the creameries of the Kilmallock district the provisions of the Order should be enforced. A long correspondence ensued and the council remained obdurate. Eventually legal proceedings were taken, as stated above, by the Local Government Board. The court unanimously refused the application, with costs against the Local Government Board, the Order being *ultra vires*. The decision is important as the Order sought to be enforced against the Kilmallock council was of general application to the country. Many other councils have also refused to obey, and others have already made these appointments, which they are now likely to cancel on short notice. The decision, in fact, is likely to render nugatory the Dairies and Cowsheds Order of 1908.

A General Anæsthetics Bill.

In view of the fact that the General Medical Council at its present session is to consider a draft of an Anæsthetics Bill sent down from the Privy Council, the President of the Royal Academy of Medicine in Ireland (Sir Charles Ball) recommended a special meeting of the Academy to consider the entire subject. As dentists are much interested in the question, the members of the Irish Branch of the British Dental Association were invited to be present and to take part in the discussion. The dentists showed more interest than the Fellows of the Academy, some dozen and a half only of the latter being present and at least twice as many dentists. After discussion the following resolutions were adopted:—

1. That it is desirable in the public interest that the administration of general anæsthetics to render persons unconscious during any medical, surgical, obstetrical, or dental operation or procedure, should be restricted by law to registered medical practitioners, with the exception of nitrous oxide gas and such other anæsthetics as may from time to time be sanctioned by the Privy Council, which may be administered by a registered dentist.
2. That provision should be made for the practical instruction in anæsthetics of medical and dental students.
3. That the specification of the anæsthetic substances or drugs which may thus be employed by registered dental practitioners during dental operations or procedures should be made in a schedule to the proposed Act of Parliament, power being reserved to the Privy Council, on the recommendation of the General Medical Council, as the authority charged with the publication of the British Pharmacopœia, to add to or vary the specified list from time to time as occasion arises.
4. That the administration of local anæsthetics for producing insensibility to pain during any surgical or dental operation or procedure by the introduction beneath the skin or mucous membrane of any fluid or other substance by means of a hypodermic needle or in any other way, should be restricted by law to registered medical practitioners, to registered dentists, or to persons acting under the immediate supervision of a registered medical practitioner or a registered dentist.

Poor-law Reform.

A conference on Poor-law reform will be held in the Mansion House, Dublin, on Wednesday, Dec. 7th. Invitations have been addressed to the clerk of each union in Ireland in the hope that one or more members of each board of guardians will attend. The object of the conference is to elicit a definite expression of opinion from guardians in favour of some one of the methods of reform which have been proposed in the report of the Viceregal and Royal Commissions. The conference has been organised by the Philanthropic Reform Association and the Irish Workhouse Association.

Conferring of Degrees in University College, Galway

Following on the conferrings of degrees in Dublin and Cork a meeting of the Senate of the National University was held last week, in University College, Galway, for the purpose of conferring degrees. It was the first time that such a ceremonial had taken place in Galway. It is gratifying to know that the scenes of disorder which took place at Dublin and Cork were not repeated in Galway.

The Ulster Medical Society.

The session 1910–11 opened on Nov. 10th. A very hearty vote of thanks, moved by Dr. H. O'Neill and seconded by Dr. A. G. Robb, having been accorded Dr. J. J. Austin, the retiring President, the incoming President (Sir Peter O'Connell) proceeded to give his introductory address on "The Present Position of the Poor-law Service in Ireland as bearing specially on the Medical Profession," and advocated a State medical service. The President invited a discussion, in which the following gentlemen joined: Dr. Robb (who said that 95 per cent. of the practitioners of Ulster and 90 per cent. of those in Connaught had signed the paper in favour of a State medical service, and he hoped that Leinster and Munster would go equally united for it), Dr. C. Kevin, Mr. R. Hall, Sir John Byers, Dr. O'Neill, Mr. W. Burns, Dr. J. S. Darling, Professor T. Sinclair, and Dr. J. Walton Browne. There was a marked unity of opinion in favour of a State medical service, which it was recognised would be best for the country, would raise the status of the medical profession in the Poor-law service, and would improve the public health of the country. On the motion of Dr. John Campbell, seconded by Dr. W. Calwell, a hearty vote of thanks was passed to the President for his address.

Women's National Health Association of Ireland.

Lady Aberdeen, founder and president of the Women's National Health Association of Ireland, spoke at the annual meeting of the Belfast branch on Nov. 8th and at Ballymena on the next day at the yearly assemblage of the Mid-Antrim branch. Very encouraging reports were presented at both meetings. In Belfast (the Lord Mayor presiding) the Moderator of the General Assembly, the Catholic and the Protestant Bishops, Dr. Marion Andrews, and Mr. H. W. Ballie

took part, while at Ballymena Mr. R. Currie and Dr. W. R. Davison addressed the meeting.

Belfast Asylum.

The report of the Inspectors of Lunatics (Dr. E. M. Courtenay and Mr. I. M. Considine) was read on Nov. 14th at a meeting of the asylum committee of the city council of Belfast. They write in the highest terms of the Purdysburn asylum and hope that no time will be lost in disposing of the old institution in Grosvenor-road, Belfast, and transferring the inmates to new quarters at Purdysburn, where they will enjoy all the advantages of country life and pure air, together with the advantage afforded by beautiful buildings and good surroundings. 1245 people are now on the books of the asylum—583 males and 662 females—792 in the old asylum at Belfast, 339 at Purdysburn, and 54 in Ballymena workhouse. The medical officers are all praised for their work and their care of the inmates.

A Case of Cerebro-spinal Meningitis in Belfast.

An inquest was held on Nov. 9th at the Recorder's Court, Townhall-street, to inquire into the death of a child aged 6 years. Professor W. St. Clair Symmers, who made a post-mortem examination, stated that death was due to cerebro-spinal meningitis.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Trephining in Simple Fractures of the Skull.

AT a meeting of the Society of Military Medicine held on Nov. 8th M. R. Picqué recommended lumbar puncture as one of the first steps in the treatment of simple fractures of the skull. He said that it was indispensable as a means of diagnosis, but a further operation was required if the general symptoms persisted after the puncture, and the surgeon should trephine as soon as the least local sign indicated the precise locality. M. Moty said that trephining was plainly indicated when there was severe intracranial pain which resisted ordinary treatment; opening and draining the arachnoid cavity distinctly relieved the pain. M. Jacob, M. Sieur, and M. Rouvilois said that lumbar puncture was sufficient in a great number of cases; they thought that systematic trephining was not necessary when the patient did not present any sign of cerebral localisation or compression and when there were only symptoms of excitement; lumbar puncture gave the patient the same advantages as trephining. In support of their opinions they quoted cases in which patients suffering from fracture of the base of the skull had recovered without any operation other than lumbar puncture.

The Floods.

The river Seine is once more in flood and rising in so alarming a manner that the inhabitants of the *banlieue* are hastily removing their furniture and leaving their homes. In Paris the water is making its way into the cellars of the houses along the quays and the steamboats have had to stop running. At Javel and at Auteuil the water washes over the wharves. The cellars of the wharves on the Quai d'Austerlitz are being emptied, ventilators on the ground-level are being closed, and it is feared that the Hôpital Boucicaut may have to be evacuated. The whole of the *banlieue* in the neighbourhood of the river is flooded and other parts are threatened. On all sides the officials of the Department of Public Works are taking measures of protection against the rising water and are endeavouring to prevent a breakdown of the supply of electric current such as the floods caused last year, with the result that tramway traffic was stopped in a great many parts of Paris.

New Organic Preparations of Arsenic.

At a meeting of the Academy of Medicine held on Nov. 8th M. Armand Gautier said that although he had not spoken on the subject of organic arsenical compounds since the year 1901 he had, nevertheless, been the first to obtain such organic preparations of arsenic as the cacodylates, the methylarsenates, and arrhenal, in which toxicity was reduced to a minimum, while their therapeutic value in certain diseases was truly remarkable. He showed that in syphilis a combination of mercury with arsenical preparations gave excellent results. Since the year 1895 the cacodylates have been employed in the Hôpital Saint-Louis, in the wards of which Dr. Danlos had charge, injections of them being given in doses varying from 0·60 gramme to 0·80 gramme per day; they have also been prescribed in the Hôtel-Dieu and the Hôpital Boucicaut.

Provincial Sanitary Conference.

The first Provincial Sanitary Conference organised by the Society of Public Medicine and Sanitary Engineering was held recently at the Pasteur Institute. Dr. Roux, who presided, said that this society last year played an important part in connexion with public health legislation, and had now brought together the superintendents of the health offices, the departmental inspectors of health, and various administrative authorities for the purpose of considering the applications of the new statute. M. Herriot, mayor of Lyons, then explained his views on the subject of modern hospitals, with especial reference to the suburban hospital which was about to be built at Lyons. It would occupy a site of 156,000 square metres and would contain 1200 beds, of which 150 would be reserved for infectious cases. M. Herriot has adopted the system of separate compartments, such as were in use at the Pasteur Institute. The hospital would naturally consist of detached pavilions, of which there were 18, all communicating by means of underground passages. The laboratories would be in the basement, the ground floor and the first floor would be occupied by patients, and the upper floors would be used for the accommodation of the officials. M. Lemoine, principal medical officer at Val de Grâce, then presented a report on the etiology and prophylaxis of typhoid fever, and a discussion followed in which M. Guillemin, M. Chantemesse, M. Zipfel, M. Panel, M. Granjux, M. Julien, M. Calmette, M. Gautrez, M. Courmont, and M. Rossi took part.

The Use of Radium in Dermatology and Rhinology.

At a meeting of the Société de Médecine de Paris, held on Nov. 11th, M. Lagarde and M. Masotti presented a communication on the Use of Radium in Dermatology and Rhinology. They said that in a number of cases patients suffering from conditions included under these headings might derive benefit from the employment of radium. This substance was already in daily use for the treatment of nævi, cancroid growths, lupus of the nose, cancers, leucoplasia, and lichen of the oro-pharynx. It seemed probable, moreover, that other tumours of the nasal fossæ (sarcomata, epitheliomata, and tuberculous growths) might benefit from the same applications, and that certain zones of the nasal mucous membrane, localities liable to polypus and varix, might be favourably influenced. Some other diseases such as maxillary sinusitis, hypertrophied tonsils, and laryngitis might also be successfully treated by radiferous substances combined with insoluble salts. Lantern pictures of patients who had recovered under this treatment were shown. In the subsequent discussion M. Druelle said that he recognised the features of one of the patients who had been shown on the screen as recovered, and he believed that this person had recently died from epithelioma in the Hôpital Saint-Louis. M. Levassort said that when photographs of patients were publicly exhibited care should be taken to make individual recognition impossible, but recognition in this case may have corrected a blunder.

A Coöperative Restaurant for Female Students.

A General Association of Female Students was formed in Paris last June, and a coöperative restaurant for the use of the members has now been established at No. 55, Rue Saint-Jacques, where a repast consisting of soup, meat, sweets or dessert, bread, and wine is provided for 1 franc; for 5 o'clock tea the charge is 25 centimes. A number of gentlemen occupying official positions attended the inaugural ceremony when the restaurant was opened on Nov. 6th, the company including M. Liard, vice-rector of the Academy; M. Lavisse, director of the École Normale Supérieure; the Presidents of the Municipal Council and of the General Council; and Professor Landouzy, dean of the Faculty of Medicine.

Nov. 14th.

Mrs. Amy Mary Macdonald, M.D., widow of the late Dr. Donald Macdonald of Stornoway, and eldest daughter of Mr. J. Galloway Weir, M.P., died at her residence, "Lyndale," Harlesden, N.W., on Monday, after a long and painful illness.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Tabes Dorsalis by Mercury.

IN a paper read before the Vienna Medical Society, Professor Redlich discussed the results obtained by him in the treatment of tabes dorsalis with mercurial preparations. His statistics were based on observations made on 308 private patients, of whom 282 were men and 26 were women—a proportion of 11 to 1. Of these patients, 44 per cent. had presented evident symptoms of syphilis, and another 26 per cent. acknowledged having had an "ulcer" without being aware of secondary manifestations, so that 70 per cent. of them were to be regarded as certainly suffering from specific infection. Wassermann's reaction was also positive in 70 per cent. of the patients examined; 19 persons with no history of syphilis gave a positive Wassermann reaction. Amongst the 308 cases of tabes only 19 per cent. had been subjected to regular antisyphilitic treatment commencing immediately after infection (whatever effect this treatment may have had it at least did not prevent the occurrence of tabes); 41 per cent. had had only an irregular treatment and 40 per cent. had had no antisyphilitic treatment at all. Professor Redlich subjected all cases to a mild mercurial course, combined with hydrotherapeutic, thermic, and gymnastic procedures. In no case did the mercury produce any unfavourable effect; several patients were distinctly benefited by it, whilst in others it had no perceptible action whatever. It was administered in moderate doses, mostly by inunction but sometimes by injections. The disease remained in a stationary condition in about 10 per cent. of the cases; in acute exacerbations mercury was decidedly indicated. A combination of tabes with progressive paralysis was not influenced at all; *crises gastriques* and atrophy of the optic nerve were very refractory. Professor Redlich thought that only cases in an early stage, and acute exacerbations of existing disease, were suitable for this mercurial treatment, and that optimistic expectations were not warranted. It could not be said that the effect of Ehrlich's new remedy, "606," was beneficial under such conditions, and it remained to be seen whether patients treated with this substance would escape subsequent tabes or paralysis.

A Debated Question of Professional Secrecy.

The death of a celebrated actor in Vienna, who also held a high position in society, has caused in medical circles renewed discussion as to the maintenance of secrecy in the relations between a patient and his medical advisers. The actor, who was an important personage in our principal theatre, was suffering from advanced internal cancer. The regularly appointed physician to the theatre, a man of high professional standing, was the first to discover the nature of the disease, and the question then arose whether or not he ought to inform his chief (the director of the theatre) as to the state of the actor's health. One prominent feature of the case was that the actor was on the point of renewing a contract with the theatre, and this would have had the effect that the performances would have been arranged on the understanding that he would appear in them. In the result the medical man decided to inform the director, but in order to avoid alarming the patient the contract was made just as if he had been in good health. Meanwhile an operation had to be performed, and when the facts became known to the public, which here is very sensitive in all matters pertaining to theatres and music, the attitude of the medical man was severely criticised from opposite points of view, some blaming him for making any disclosure at all and others for having withheld what ought to have been made known. Needless to say, the medical man soon pointed out that the public was not entitled to any information which he might possess regarding the actor's personal health; and he also maintained that with respect to the director of the theatre, he was in a position comparable to that of a medical man to an insurance company or other corporation, in being obliged to disclose to his employer the diseases from which patients suffered. In medical circles he is exonerated from blame, but the public seem to be unwilling to accept his explanations.

An Austrian Cancer Committee.

The results obtained in other countries have led to the formation in Austria of a committee with a view of combating cancer. The original members of this committee are Professor von Eiselsberg, Professor Fränkel, Professor Hochenegg, Professor Schauta, Professor Paltauf, and Professor Weichselbaum, these being the leading surgeons, gynæcologists, and pathologists respectively of the University of Vienna. As soon as the preliminary work of the committee is finished a Cancer Society will be constituted. This society will draw the attention of the general public to the necessity of seeking medical advice at the very earliest appearance of suspicious symptoms, but its principal object will naturally be the prosecution of scientific research. Lectures and discussions dealing with this subject, periodical publication of the work accomplished by its members, and grants for the promotion of original investigation will be the leading features of the programme of the Cancer Society. Some time ago, when Professor Chrobak was at the head of the Vienna Medical Society, similar action was taken, when a leaflet entitled "Principiis Obsta" ("At the Commencement") was distributed amongst the female patients in the Vienna hospitals in order to draw their attention to such symptoms as required careful observation.

The New Radium Institute.

The new Radium Institute, the largest of its kind, was recently opened with much ceremonial display in presence of His Imperial Highness the Archduke Reiner, the Protector of the Academy of Sciences. The institute has been established by an anonymous gift to the Academy, the only stipulation being that the institute must be erected before the end of the year 1910. The entire outfit has also been provided by private liberality. The institute will be devoted to research only, and will not be used for teaching purposes. It has two distinct departments, intended respectively for physical and for chemical research. The latter, which will, for instance, undertake the determination of atomic weights, is situated in the basement and first floor of the building. On the first floor there is also the apparatus for the examination of waters and minerals for radio-activity, as well as for similar investigations in regard to air collected at different places. The institute possesses a total quantity of 3 grammes of radium bromide, valued at 1,000,000 kronen, or £45,000, presented by the Academy of Sciences of Austria. The investigation of the atomic weight of radium will be entrusted to Dr. Hönigschmidt; researches will also be carried on for the standardisation of radio-activity by determining an international unit for this purpose. The Congress for Radiology held in Brussels elected an international committee for the purpose of deciding on such a unit, the Austrian representatives being Professor Stephen Meyer and Professor Schweidler. The institute has no lecture-hall, being entirely restricted to research, and medical treatment will not be within the scope of its work.

Nov. 14th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Public Health.

THE invalid and the valetudinarian—a "constant quantity," if not an increasing one, in the annual contingent of foreign travel—need be under no misgiving in setting out for this or that Italian health resort in quest of warm, salubrious air and immunity from "epidemics," prevailing or sporadic. Alarmist reports notwithstanding—reports, as I have authority for stating, industriously diffused from transalpine quarters, where "warnings" against a sojourn in Italy are even printed on the *menu* of many a *table d'hôte*—the cities and seaboards of the Italian mainland and islands are as safe as ever they were for the foreign visitor. Cholera is practically *une quantité négligéable*, as the following figures, officially checked and countersigned, will suffice to prove. From midnight to midnight of one day last week there was in the province of Girgenti (Sicily) but one case and no death; in the province of Palermo one case and no death; in the province of Lecce two cases and no death; in the province of Caserta (Neapolitan) two new cases and one death of a patient previously notified; in the province of Rome one case at Tarrácina (Pomptine Marshes) and no death; while of the previously notified cases bacteriological examination has given positive results in one

case at Brindisi and two at Cancello Arnone and a negative result in one at Brindisi. In fact, but for the undoubted presence of the disease in Southern Italy these last few weeks the cases now reported would have passed unnoticed, except by the State experts; certainly they would have caused no alarm in the resident, and acted as no deterrent to the foreigner. Another point may be indicated as distinctly reassuring. In those cases where the disease has been bacteriologically ascertained, recoveries have been far more frequent than deaths, clearly proving that medical treatment, immensely more efficient than in past visitations, has robbed the "Asiatic intruder" of some portion of his terrors. All the same, the reports above referred to are still active and effective enough to deter the travelling world from its accustomed resort to Italy this autumn, and hotel-keepers throughout the kingdom may well be downcast. I know of several well-appointed establishments, justly held in high repute by the English-speaking visitor, which for weeks past have been able to boast of but one guest—a "Robinson Crusoe" vainly looking out for a "Man Friday."

The Weather.

Rarely has the Storm King run such riot throughout the Italian mainland and islands as during the last ten days, and only now are we beginning to realise the width and depth of the damage and misery he has left behind. On the Neapolitan Riviera bodies swept out to sea from the island of Ischia by the recent "nubifragio" are being fished up from time to time, leaving many others unaccounted for, except on the hypothesis that they have been, as was found after the Siculo-Calabrian cataclysm of Dec. 28th, 1908, devoured by sharks. What with earthquakes, cyclones, cloudbursts, and inundations, southern and even central Italy has had experience enough, telluric and atmospheric, to make the year now closing an "annus mirabilis." Decade by decade such visitations become frequent enough to warrant a claim to "periodicity," and to justify the French nature-student, in these latitudes especially, when he cried, "Ah! Monsieur, la terre est si nerveuse!" Meteorology, nowhere more assiduously than at the Italian observatories, is working at the causes of these perturbations, coincident with, if not consequent upon, "liberties taken with the earth's crust," in tree-felling and mining particularly. Grateful, indeed, will the world be if, in the French phrase, "la pathologie tellurique" rewards its students with knowledge enough to restore health and stability to the soil and equilibrium to the atmosphere—doubly grateful in the near future when aerial navigation tends to supplement, if not to replace, the terrestrial locomotion now hardly capable of further development.

Alpine Misadventure.

For the year ending on Oct. 31st there were 90 deaths incurred by mountaineers, expert or amateur, on the Swiss and Italian ranges, and 80 cases of injury, of which four are expected to end, if they have not already ended, fatally. The causes were the traditional ones—to wit, starting without a guide, avalanches, detachment of rocks, snapping asunder of ropes, sudden mists, and heart failure while "clearing" a crevasse or "negotiating" an awkward or risky corner. It is no longer the Englishman who makes himself a "candidate" for such a fate—the majority of victims having been Swiss, then Germans, then Englishmen, Austro-Hungarians and Italians coming next. Aviation, however, bids fair to outstrip "peak-storming" in its death roll if the present year's statistics are to be taken as earnest of the future.

Nov. 12th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The Physical Condition of Army Officers.

General Leonard Wood has issued an army order to the effect that all officers serving in the Department of the East shall take such constant and regular physical exercise as may be necessary to keep themselves at all times in physical condition to perform active duty with troops under war conditions. Post commanders are directed to arrange schemes for the exercise of officers under their command. All officers, save under certain specified conditions, are to exercise, preferably in the open, at least one hour a day, the standard being "a ride of four miles, or a walk of three miles within an hour," with the permissible substitution of "equivalent athletic sports or exercises" for variation. The order seems to be generally accepted in army circles as an excellent thing. General Wood has already shown the advantages of such training in the promotion of sanitation and hygiene in the army; it is, he believes, a factor of prime importance in the efficiency of troops as a fighting machine.

Pasteurised Milk for Infants in New York.

Mr. Nathan Straus, who now for some years has maintained at his own expense in New York depôts for the supply of pasteurised milk for the feeding of the infants of the poor, a few weeks ago announced his intention of discontinuing them because of the continual criticism of his methods. As the progressive decrease in the infant death-rate in that city seems to have been due in a considerable measure to his efforts, many citizens considered that until the city should be ready to continue his work the closing of these depôts would be a public calamity. A mass meeting was accordingly held on Oct. 8th at the Cooper Union, in which many prominent men, including such well-known persons as Professor Irving Fisher (of Yale), Father J. J. Curran, Commissioner C. J. Driscoll, Dr. Abraham Jacobi, and Secretary of State Koenig, were present. The meeting was attended by some 2000 people. The service rendered to the community by Mr. Straus's philanthropic efforts on behalf of the children of the poor was gratefully and gracefully acknowledged, and means were discussed of continuing the work in case Mr. Straus could not be induced to rescind his expressed determination. On Oct. 24th Mr. Straus held a conference with a committee appointed at a meeting of philanthropic agencies held on Sept. 7th, and as a result of its appeal he will continue for awhile the work initiated by him, in the hope that the city may take it up, and that other depôts in addition to the eight already sustained by himself may be opened by the efforts of others.

Prophylaxis against Cholera.

The Public Health and Marine Hospital Service is showing praiseworthy activity in respect of the threatened danger of the introduction of cholera into the United States. A death from cholera in quarantine at New York on an incoming vessel, and the subsequent development of another case on the same vessel, led to the instant coöperation of the service with the State health authorities. Intending emigrants to the United States from infected ports abroad are now detained for five days before being allowed to sail, and are again detained for the same space of time here in quarantine before being allowed to land. On release from quarantine such suspects will have to state their destinations, and information cards will be forwarded each day to the health officer of each place to which such persons are going, so that they may be kept under observation. A notable circumstance is the absence of panic following the discovery of the arrival of cholera cases in this country, a difference from the public emotion which followed the introduction of the disease on previous occasions, notably in 1892. This is a good sign of the increasing confidence in the effectiveness of official vigilance.

Abolition of the Public Drinking Cup.

Boston has abolished, under a regulation of the Massachusetts State Board of Health, the use of the public drinking cup in public parks, streets, buildings or premises used as a public hotel, theatre, public hall, or public school, railway station or car, steamboat or ferry-boat. Bubbling drinking fountains have been installed in many places and individual paper cups are rapidly being adopted.

The Antituberculosis Campaign.

The new Sanatorium Directory, issued by the National Association for the Study and Prevention of Tuberculosis, shows over 400 sanatoriums and hospitals, 300 special tuberculosis dispensaries, and some 450 special antituberculosis associations and committees now existing in the United States. The first such directory was issued in 1904, and showed only 133 sanatoriums and hospitals, 32 special dispensaries, and 39 antituberculosis organisations; so that the increase in the last six years in antituberculosis agencies amounts to nearly 500 per cent. The directory also contains a summary of what has been effected by the various State legislatures and county and municipal governments in aid of the war against tuberculosis in this country.

Nov. 8th.

Obituary.

DR. LANCEREAUX.

Dr. Lancereaux has just died at the age of 80 years after a few days' illness from pneumonia. He was born at Brécy-Brières, in the Ardennes, on Nov. 27th, 1829, and during the early part of his professional career was in somewhat straitened circumstances, but his energy and capacity for work eventually raised him to a position of eminence. He was admitted *interne* in 1857, hospital physician in 1869, *agrégé* in 1872, and member of the Academy of Medicine in the Section of Pathological Anatomy in 1877, becoming president of the Academy in 1908. He made a number of original investigations, chiefly on questions of pathology, and in studying the lesions discovered post mortem he always endeavoured to trace their connexion with the symptoms observed during life. At first he interested himself mainly in disorders of the nervous system. His researches on nervous diseases due to syphilis were published at the end of his *internat* in 1861; his thesis on cerebral thrombosis and embolism appeared in the same year, and his memoir on meningeal hæmorrhage in 1863. Soon after this period he began to apply himself to the study of organic diseases produced by certain toxic agents; lead palsy and other

symptoms of lead poisoning were among the subjects on which he now worked, but it was in connexion with the visceral lesions attributable to the use of alcoholic beverages that his views attracted most attention. In consequence of the diversity of their composition such beverages act on the system in a variety of ways, and Dr. Lancereaux in elaborating this idea has given a clinical description of the special symptoms produced by absinthe-drinking. Subsequent researches on similar lines led him to the conclusion that the disease known as alcoholic cirrhosis was not one of the ordinary ills of life to which any kind of fermented liquor might give rise. Taking for granted that it occurred in wine-drinkers only, he sought for the toxic agent and convinced himself that it was neither alcohol nor any product of the vinous fermentation, but a mineral salt, bisulphate of potassium, and experiments which have been made on animals seem to confirm this view.

Dr. Lancereaux published a considerable number of works, including an Atlas of Pathological Anatomy, which appeared in 1871; an Historical and Practical Treatise on Syphilis in 1866 (with a second edition in 1873); a Treatise on Pathological Anatomy in 1875–85; a Treatise on Herpes in 1883; various volumes of clinical lectures in 1883, 1890, 1892, and 1894; a Treatise on Diseases of the Liver and Pancreas in 1899; and quite recently a Treatise on Gout. One of his most important discoveries was the relationship between diabetes and disease of the pancreas. Several observers had preceded him in remarking the frequency of lesions of the pancreas in diabetes, but he had the merit of recognising that a form of the latter disease with characteristic clinical symptoms—wasting diabetes—dependeo on inadequacy and ultimate destruction of the pancreas. It was in 1877 that he pointed out the special features of this condition—namely, the sudden onset, the immediate loss of flesh, the intense thirst and craving for food, and the rapid progress of the disease. On clinical and pathological grounds he called it pancreatic diabetes, a designation which has been justified by the subsequent observations of von Mering and Minkowski.

HUGH NORRIS, L.R.C.P., L.R.C.S. EDIN., L.S.A.

Mr. Hugh Norris died recently at his residence in South Petherton, Somerset, in his ninetieth year. Mr. Norris was born at South Petherton, where his father was a well-known medical practitioner and archæologist. He belonged to a very old Somerset family. His grandfather, Henry Norris, a famous schoolmaster at Taunton, is stated on a tablet in St. James's Church in that town to have been proficient in 24 languages, while another member of the family founded the first Taunton newspaper in 1725. In 1554 an ancestor, John Norris, represented Taunton in Parliament, and during the Civil War another member of the Norris family raised a troop of horse for King Charles.

Hugh Norris received his medical education at Edinburgh University and qualified L.R.C.S. of Edinburgh in 1848, being admitted L.R.C.P. of Edinburgh ten years later. After holding resident appointments at the Royal Maternity Hospital, Edinburgh, he joined his father in practice at South Petherton, where he soon became very popular. Shortly after settling down to practice he drew attention to a state of defective mental development associated with bodily deformity or arrested growth which existed in the village of Chiselborough, near South Petherton, in the "forties" of the last century. A correspondent writes as follows to us about Norris's observations:—

> Chiselborough is situated in a small valley closely surrounded on three sides by hills, about 400 or 500 feet in height, and at the time of the existence of this uncommon disease the lowest part was very damp and dirty, the temperature being very mild, and the village was open only towards the west, where flowed a deep sluggish river called the Parrett. In recording the occurrence Mr. Norris described the inhabitants as "unfortunate beings," exceedingly unprepossessing, small in stature—one, a female, aged 30, only reaching three feet and a half—and in most cases thick-set. Their heads were large and covered with a profusion of very coarse ragged or bristly hair of a dark brown colour, while their limbs were bony and exceedingly ill-formed. The contour of the face was wide and flat, forehead very low, and slightly receding. The eyes were small and sunken, the nose flat, almost like that of a negro, the mouth large, and the lips thick. The walk of these cretins, if they might be so called, was most ungainly, and resembled more the waddle of a duck while they were generally very weakly both physically and intellectually. Out of a population of about 540 Mr. Norris found some twenty were idiots, while the majority had an obvious deficiency of intellect, were more than usually dull of perception, had a very marked impediment in their speech, and were, he believed, without an exception, affected with the disease known as bronchocele. He was of opinion that the cause of the malady was the effect of a combination of circumstances. The water was of a very inferior quality, the air very impure from the absence of any current through the village in consequence of its being so closely hemmed in on three sides by hills, as well as from a great quantity of decaying vegetable matter at certain seasons of the year arising from the orchards in the immediate neighbourhood, while several stagnant pools also existed in the place. Circumstances such as these combined to render the village so uninviting to strangers that intermarriage among the poor inhabitants was most prevalent; and thus, said Mr. Norris, was unwittingly completed the unfortunate combination of circumstances which may have produced such miserable results.

We are unaware if this vivid piece of clinical observation received the attention which it would seem to have deserved.

Mr. Norris took a great interest in archæological pursuits, as did his father before him, and formed an interesting collection of great local archæological value, which he presented to the county museum at Taunton, where it is known as the "Norris Collection." He had at one time an extensive practice in West Somerset but for several years he had retired from active work. In his younger days his literary bias was strong and he contributed articles to THE LANCET and other medical papers, and was besides the author of an interesting topographical note, "South Petherton in the Olden Time,"

as well as of several instructive papers communicated to the Somerset Archæological Society; while he was the first editor of "Somerset and Dorset Notes and Queries."

The funeral took place at South Petherton on Nov. 4th.

VIOLET ACKROYD TURKHUD, M.D., B.S. LOND.

THE medical women of India have lost a colleague by the death of Miss Violet Ackroyd Turkhud in Bombay from enteric fever. She was educated at Bedford College and the London School of Medicine for Women. She qualified in 1906, taking the degree of M.B., B.S. Lond. After some post-graduate work in England, she went to India, where for some months she was on the staff of the Dufferin Hospital, Delhi. Next she was in charge of the Women's Hospital, Alwar. In 1909 she returned to England and took the degree of M.D. Lond., with honours in pathology. After working for some months at the School of Tropical Medicine, Liverpool, she obtained the Diploma in Public Health. In February, 1910, she went back to India and began a practice in Bombay. She was engaged in research work in pathology at the Cancer Hospital for some months before her death, which occurred on Oct. 18th. Her cheeriness of disposition made her universally popular. She was a keen student and an enthusiastic worker in her profession, and her untimely death, at the beginning of what promised to be a most useful and distinguished career, is mourned by a wide circle of friends both in India and in England.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians of London on Oct. 27th, and of the Council of the Royal College of Surgeons of England on Nov. 10th, Diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following gentlemen, who have passed the Final Examination of the Conjoint Examining Board and have complied with the by-laws of the Colleges:—

William Arthur Anderson, B.A.Cantab., Cambridge University and Queen's College, Belfast; Richard William Annison, Middlesex Hospital; Sydney Vere Appleyard, St. Thomas's Hospital; Helton Godwin Baynes, Cambridge University and St. Bartholomew's Hospital; Benjamin Bernstein, London Hospital; Guy Capper Birt, L.D.S. Eng., St. Thomas's Hospital; Aleck William Bourne, B.A. Cantab., Cambridge University and St. Mary's Hospital; Edmund Boyd, B.A., M.B. Toronto, Toronto University and University College Hospital; Edward Geoffrey Stayner Cane, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; William Edgar Carter, Leeds University; Alfred Ernest Dagnall Clark, St. Bartholomew's Hospital; Guy Barton Cockrem, Guy's Hospital; Leonard Kingsford Cooper, University College Hospital; James Cowan, Manchester University; Oswald Tilson Dinnick, M.B. Toronto, Toronto University and London Hospital; Arthur William Donaldson, Oxford University and St. Thomas's Hospital; Sandbrook Falkner, London Hospital; *Walter Egbert Fox, Guy's Hospital; Alfred John Gibson, St. Bartholomew's Hospital; Alexander Kennedy Glen, Glasgow University, St. Mary's and Middlesex Hospitals; Wilfrid Montague Glenister, St. Bartholomew's Hospital; Ernest St. George Sagar Goodwin, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Frank Cyril Greig, Otago University and University College Hospital; Alexander Keith Hamilton, St. Thomas's Hospital; Hubert Alfred Harris, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Arthur Stanley Heale, London Hospital; Augustus Joseph Hickey, Westminster Hospital; Arthur Hilary Clifton Hill, Middlesex Hospital; John Percival Hill, M.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Jordan Constantine John, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; William Henry Talfourd Jones, King's College and Guy's Hospitals; Joseph Bagnall Jordan, Birmingham University; Theodore Hartmann Just, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Charles Dones Killpack, Guy's Hospital; Clifford Yule Laing, Manchester University; William Bertram Laurence, University College, Cardiff, and Middlesex Hospital; Martin Wentworth Littlewood, St. Thomas's Hospital; Albert Victor McMaster, B.A., Queen's College, Belfast, and London Hospital; Godfrey Kindersley Maurice, St. Mary's Hospital; Rustom Dhunjibhoy Mody, L.M.S. Bombay, Bombay University and University College Hospital; Carl Euclid Molino, Birmingham University; Gustave Jean Philippe Monod, M.D. Paris, Paris University; Raymond Montgomery, Leeds University and Guy's Hospital; Albert Ernest Moore, London Hospital; Gilbert Moore, Cambridge University and King's College Hospital; Henry Clarence Wardleworth Nuttall, Liverpool University; Charles Edward Hewitt Paley, Westminster Hospital; Georg Natanael Palmaer, London Hospital; Henry Brice Parker, Bristol University and London Hospital; Ardeshir Beheramshah Pestonji, B.A., L.M.S. Bombay, Bombay University and London Hospital; Harold Ferdinand Renton, Leeds University and Guy's Hospital; William Reynolds, L.D.S. Eng., Guy's Hospital; Quintin Hume Richardson, Guy's Hospital; Behram Pestonjee Sabawala, L.M.S. Bombay, Bombay University and London Hospital; Herbert Henry Sampson, M.B., Ch.B. Birm., Birmingham University; Alexander Rutherford Prinski Scott, London Hospital; William Faulkner Valentine Simpson, London Hospital; Charles James Stocker, Cambridge University and St. Bartholomew's Hospital; Martin Phillips Thomas, Glasgow University, Cardiff and University College Hospitals; Graham Yalden Thomson, Guy's Hospital; Richard Teodor Timberg, St. Mary's and St. Thomas's Hospitals; Henry Shemeld Tumber, Sheffield University; Arthur Bayford Guy Underwood, University College Hospital; Wallace Robert Wade, M.B., Ch.B. Liverpool, Liverpool University; Percy Boyd Wallis, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Hugh Wetherbee, London Hospital; *Edward Vernon Whitby, M.B., Ch.B. Birm., Birmingham University; and Sydney Williams, University College, Cardiff, and London Hospital.

* Diploma of M.R.C.S. conferred on Oct. 13th, 1910.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination in Anatomy and Physiology for the Diploma of Fellow, held on Nov 3rd, 4th, 8th, 9th, 10th, and 11th, 117 candidates presented themselves, of whom 39 were approved and 78 were rejected. The following is a list of the successful candidates:—

Casement Gordon Aickin, M.B., Ch.B. Otago, Otago University and Middlesex Hospital; Francis Gordon Bell, M.B., Ch.B. Edin., Edinburgh University and King's College; Ellis Campbell Bowden, London Hospital; Geoffrey Williams Carte, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Arthur Chance, B.A., Trinity College, Dublin, National University of Ireland; James Harris Connolly, M.D., Ch.B. Edin., Edinburgh University and London Hospital; Charles Harold Crawshaw, B.A. Cantab., Cambridge University and King's College; Michael Joseph Cronin, London Hospital; Francis Eldon Daunt, St. Thomas's Hospital; Hector Wynne Davies, University College; Richard Denis Davy, London Hospital; George Rowland Dobrashian, University College; Victor William Draper, B.Sc. Lond., King's College; John Everidge, L.R.C.P., M.R.C.S., King's College; Philip Ferguson, M.B., Ch.B. Manch., Manchester University and London Hospital; Walter Barham Foley, St. Thomas's Hospital; Philip Julius Franklin, L.R.C.P., M.R.C.S., King's College and Middlesex Hospital; Henry George Frean, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and London Hospital; Robert Coltart Harkness, M.B., Ch.B. Edin., Edinburgh and Manchester Universities and King's College; Charles Colgate Holman, B.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and Guy's Hospital; Robert Lister Horton, University College; Cecil Meredyth Jones, University College, Cardiff, and Westminster Hospital; Charles Matheson Kennedy, L.R.C.P., M.R.C.S., London Hospital; Farquhar McGillivray Loughnane, St. Thomas's Hospital; Robert John McConnell, Belfast University and London Hospital; Kenneth Mackenzie, M.B., Ch.B. Edin., Otago and Edinburgh Universities and King's College; Henry Price Malcolm, Queen's University, Belfast, and London Hospital; Henry Hugh Mathias, Cambridge University and London Hospital; Jivray Narayan Mehta, L.M.S. Bombay, Bombay University and London Hospital; Alexander Croydon Palmer, L.R.C.P., M.R.C.S., London Hospital; Joseph Michael Petty, B.A. Cantab., Cambridge University and King's College; Edward Rayner, B.A. Cantab., Cambridge University and St. Thomas's Hospital; John Magnus Redding, Charing Cross Hospital; Pierre Roux, London Hospital; John Thompson, M.B., B.S., B.Sc. Lond., M.B., Ch.B. Vict., Manchester University and London Hospital; John Raymond Waddy, B.A. Cantab., Cambridge University and King's College; Gilbert Bertram Warburton, M.B., Ch.B. Manch., Manchester University; David Waterston, M.D., M.Ch., F.R.C.S. Edin., Edinburgh University and King's College; and Syer Barrington White, B.A. Oxon., Oxford University and Westminster Hospital.

At a meeting of the Council on Nov. 10th licences to practise dentistry were conferred upon the following gentlemen, who have now complied with the by-laws:—

Percy George Hastings Cox-Moore, Charing Cross and Royal Dental Hospitals; George Vivian Dymott, Guy's Hospital; John Trude Fripp, Middlesex and National Dental Hospitals; Arthur William Johnson, Charing Cross and Royal Dental Hospitals; and John Knowles, Charing Cross and Royal Dental Hospitals.

At the First Professional Examination for the Licence in Dental Surgery held this month the following gentlemen were approved in the under mentioned subjects:—

Mechanical Dentistry and Dental Metallurgy.—Henry John Farrow Alexander, Royal Dental Hospital; Oswald Gelling Aylen, Charles Layton Balkwill, and Horace Edgar Bampton, Birmingham University; Victor Louis Sydney Beckett, Royal Dental Hospital; David Cohen Bernstein, Birmingham University; Charles Cecil Blundell, Royal Dental Hospital; Robert Leslie Booth, Birmingham University; Alan Darcy Buck, Guy's Hospital; Cyril Holland Child, Royal Dental Hospital; James Percy Cocker, Leeds University; Herbert Howard Cooke, Royal Dental Hospital; George Basil Cooksey, Liverpool University; Eric Sutton Dickin, Liverpool University; Gilbert George Ellis, Manchester University; Louis Edward Forster, Liverpool University; John Harvey Havers Griffin, Guy's Hospital; Robert Karl Gundlach, Royal Dental Hospital; John Gordon Harris, Manchester University; Harold Harvey, Birmingham University; Thomas Eric Henderson and Montagu Fred Hopson, Guy's Hospital; George Denis Iles, Leeds University; Andrew Lawrey, Iorwerth Hubert Lloyd-Williams, William Douglas McDonald, Gerald Struan Marshall, and William Henry Matthews, Royal Dental Hospital; Donald Bernard Morrish, Guy's Hospital; Charles Edward Murch, National Dental Hospital; Hugh Bertram Neely, Guy's Hospital; Charles Justin O'Callaghan, Royal Dental Hospital; William Parry, Liverpool University; Ivan Wallace Pasmore, Guy's Hospital; Arthur Norman Paul, Royal Dental Hospital; Leonard Robert Pickett, Guy's Hospital; Gilbert John

Stuart Rose, National Dental Hospital; Max Schneider, Guy's Hospital; Sydney Frank Simpson and William Joseph Singleton, Royal Dental Hospital; Frank Bedford Stradling and Whalley Seath Stranack, Guy's Hospital; Percival Washington Symons, Royal Dental Hospital; Sidney Thomas Taylor, National Dental Hospital; John Alphonsus Tighe, Royal Dental Hospital; Thomas Bernice Tustian, Guy's Hospital; George Lotan Venning, National Dental Hospital; and Reginald Wallace White, Royal Dental Hospital.

Mechanical Dentistry.—Patrick Boyle, Royal Dental Hospital; Arnold John Chapman, Guy's Hospital; Edmund Rupert Dermer, National Dental Hospital; Philip Louis Ealand, Bristol University; Clementson Glover, Guy's Hospital; George Hobbs, Birmingham University; Charles Henry Housden, Guy's Hospital; Michael William Joseph and Denis Foster Lewis, Birmingham University; Lancelot Turtle Montgomery, Raphael Neft, Percy John Peatfield, Charles Joseph Phillips, and John Hampden Ross, Guy's Hospital; Leslie Shovelton, Birmingham University; and Joseph Leslie Tucker, Royal Dental Hospital.

Dental Metallurgy.—Marcel Adé, Lausanne University; Francis Edward Stuart Brailsford, Royal Dental Hospital; Ralph Alexander Broderick, Birmingham University; Henry O'Neil Butler, Montague Kempston Butler, and Gordon Robert Craig, Royal Dental Hospital; Gwilym Tremain Davies, National Dental Hospital; Harold Graham Elliott and William Trevor Flooks, Guy's Hospital; William Francis Gawne, Liverpool University; Walter Henry Glover and Ernest Sharman Huckett, Guy's Hospital; Hubert Humphry, Royal Dental Hospital; Bertrand Kemp Jackson and Reginald Charles Kershaw, Liverpool University; John Farnham Mace, Birmingham University; Gustavus Leigh Pemberton, Guy's Hospital; Arthur Ridges Rowe, National Dental Hospital; Archibald Frank Salsbury, Guy's Hospital; Alan Douglas Edward Shefford, National Dental Hospital; and Frank Wisher, Guy's Hospital.

DONATIONS AND BEQUESTS.—Queen Alexandra has given £100 to the Prince Francis of Teck Memorial Fund. Among the gifts promised is one of £2000 "In Memoriam."

THE NOBEL PRIZES.—The Nobel Prize for chemistry, which amounts to 195,285 francs (£7811) has been awarded to Professor Otto Wallach of Göttingen University.

MEDICAL FEES AT THE LYME REGIS COTTAGE HOSPITAL.—At the annual meeting of the subscribers of the Lyme Regis (Dorset) Cottage Hospital, which was held on Nov. 3rd, some discussion arose in reference to the question of fees. A subscriber stated that some of the patients at the institution had had to pay for the services of the medical man, and this, he contended, was entirely against the principles of a cottage hospital. The chairman, in reply, said one of the rules stated "that those patients who in the opinion of the finance committee could afford to pay the medical attendant's fees should do so," and he added that if any medical officer charged fees without the finance committee's sanction he infringed that rule. After some discussion a subcommittee was appointed to confer with the medical officers on the matter.

MEDICAL FEES UNDER THE MIDWIVES ACT.—The Woolwich borough council has sent a circular letter to the other metropolitan borough councils with reference to the provisions of Section 17 of the Midwives Bill, relating to the payment by boards of guardians of fees to medical practitioners summoned upon the advice of a certified midwife in cases of emergency, more particularly in cases of infants suffering from inflammation of the eyes. The letter states that the Woolwich borough council is strongly of opinion that the London County Council should be the authority to pay the fees of medical practitioners instead of the board of guardians, and that the Lord President of the Council has been asked to amend the Bill in the direction indicated. The other metropolitan borough councils are requested to take similar action.

UNIVERSITY OF OXFORD: RADCLIFFE PRIZE, 1910–1911.—The next award for this prize will be in the year 1911. The prize, which is of the value of £50, is awarded by the Master and Fellows of University College every second year for research in any branch of medical science comprised under the following heads: Human anatomy, physiology, pharmacology, pathology, medicine, surgery, obstetrics, gynæcology, forensic medicine, hygiene. The prize is open to all graduates of the University who shall have proceeded or shall be proceeding to a medical degree in the University. Candidates must not have exceeded 12 years from the date of passing the last examination for the degree of Bachelor of Arts and must not at the date of application be Fellows on the foundation of Dr. John Radcliffe. Candidates must send in their memoirs to the University Registry on or before Dec. 1st, 1910. The award will be made in March, 1911.

THE ROCKEFELLER INSTITUTE.—The following appointments have been made to the staff of the Rockefeller Institute for Medical Research: Dr. Francis Henry McCrudden, Dr. Thomas S. Githens, Dr. James B. Murphy, Dr. A. R. Dochez, Dr. F. Medigreceanu, and Dr. W. H. Manwaring.

NEW CHEMICAL LABORATORIES AT UNIVERSITY COLLEGE, LONDON.—In April we brought before our readers an appeal for £70,000 for providing new chemical laboratories at University College, London, including the purchase of a site in Gower-place. The death of the King a few days before the date arranged for a meeting at the Mansion House, and the consequent postponement of the meeting gave a check to the work of the appeal committee. Sir Henry Roscoe, chairman of the appeal committee, has now laid before the public the urgency of the situation in which the appeal is placed. The appeal has two objects. The first is to raise a sum of £25,000 for the acquisition of the proposed site which adjoins the College, and which, Sir Henry Roscoe points out, is an eminently suitable one. The second is to raise £45,000 to erect the laboratories. The sum of £25,000 must be raised before next Christmas Day if the Senate of the University is to be in a position to exercise the option which it holds to purchase the site. Towards this sum the committee has collected over £9000, leaving a balance of £16,000 to be raised forthwith. The sum which has been already collected has come to a large extent from members of the University and friends of the College. The Chancellor, Lord Rosebery, has headed the subscription list with £1000. Substantial help has also been given by the City Companies and by several prominent business houses. The Drapers' Company have promised £500, provided the site is secured before the expiry of the option. The Merchant Taylors' Company have promised £262 10*s.*, while the Grocers' Company have contributed £250 and the Fishmongers' Company £105. With respect to the contributions from business houses it may be mentioned that the Liebig's Extract of Meat Company have contributed £105, while Messrs. Glyn, Mills, Currie and Co. and Messrs. Spencer, Chapman, and Messel have each given £100. Other important contributions are £500 each from His Grace the Duke of Bedford, Mr. Otto Beit, and Mr. James Eccles. Sir Henry Roscoe appeals "to all those who realise the national importance of scientific research and its bearing upon the commercial prosperity of the country, to those Londoners who desire to see university teaching in London developed in accordance with the needs of the nation, and also to the many friends and admirers of Sir William Ramsay, the Professor of General and Inorganic Chemistry at University College, to assist in the attempt to provide new chemical laboratories by gifts which will ensure the acquisition of the site." Donations should be addressed to Sir Henry Roscoe at University College, London.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BERKELEY, COMYNS, M.B., B.C. Cantab., F.R.C.P. Lond., has been appointed an Examiner in Obstetrics at the University of Oxford.

BUNN, R. A., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

CUNNING, JOSEPH, M.B., B.S. Melb., F.R.C.S. Eng., has been appointed Surgeon to the Cancer Hospital.

CUSHNY, A. R., M.B., M.S. Aberd., has been appointed an Examiner in Materia Medica at the University of Oxford.

DALTON, ERNEST C., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

DODDS-PARKER, A. P., M.B., B.S. Oxon., F.R.C.S. Eng., has been appointed an Examiner in Human Anatomy at the University of Oxford.

GOTCH, FRANCIS, M.R.C.S., F.R.S., has been appointed an Examiner in Physiology at the University of Oxford.

GOVAN, ROBERT, M.B., B.S. Glasg., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

HOPE, CHARLES W. M., M.D. Durh., F.R.C.S. Eng., has been appointed Assistant Surgeon to Golden-square Throat Hospital, W.

HUGHES, W. STANLEY, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Superintendent of the North Wales Asylum.
ILLINGTON, E. M., Major, I.M.S., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
KIDD, PERCY, M.D. Oxon., F.R.C.P. Lond., has been appointed an Examiner in Medicine at the University of Oxford.
LEISHMAN, Sir WILLIAM B., M.B., M.S. Glasg., has been appointed an Examiner in Pathology at the University of Oxford.
LOOSELY, CHARLES J., M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Hospital for Sick Children, Great Ormond-street, W.C.
MILNE, CHARLES, Major, I.M.S., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
NEVY, C O., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
PRIDMORE, J. W., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ryde District of the Isle of Wight.
REES, W. T., M.R.C.S., L.S.A., has been appointed Medical Officer to the Llanwrtyd Urban District Council.
RUSSELL, M. J., L.R.C.P. & S. Irel., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
SMITH, F. J., M.D. Oxon., F.R.C.P. Lond., has been appointed an Examiner in Forensic Medicine and Hygiene at the University of Oxford.
STIFF, H. H., M.B. Cantab., has been appointed Medical Attendant to the Alexandra Home for Children, Bury St. Edmunds.
TAGGART, C. C., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
TREADGOLD, H. A., L.R.C.P. Lond., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
WHITTON, JAMES, M.D. Irel., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.
WRIGHT, GARNETT, M.B., Ch.B. Edin., F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Salford Royal Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon, also House Surgeon, both for six months. Salary £100 and £50 per annum respectively, with board, residence, and washing.
BETHLEM HOSPITAL.—Resident House Physician, unmarried, for six months. Salary at rate of £25 per quarter, with apartments, board, and washing.
BERWICK, COUNTY OF.—Medical Officer of Health. Salary £400 per annum.
BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Resident Surgical Officer. Salary £100 per annum, with board and attendance.
BODMIN, CORNWALL COUNTY COUNCIL.—County Medical Officer of Health. Salary £500 per annum.
BRISTOL ROYAL INFIRMARY.—Honorary Dental Anæsthetist.
CARDIFF INFIRMARY (GENERAL HOSPITAL).—Senior Resident Medical Officer. Salary £120 per annum, with board, washing, and apartments. Also House Surgeon for six months. Salary £30, with board, residence, and laundry.
COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.
DUBLIN, ROYAL HOSPITAL FOR INCURABLES, Donnybrook.—Resident Medical Officer, unmarried. Salary £120 per annum, with board and apartments.
EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Also Medical Officer for six months. Salary at rate of £100 per annum, with luncheon and tea provided.
EDMONTON UNION INFIRMARY, Bridport-road, Upper Edmonton.—Two Resident Assistant Medical Officers, unmarried. Salary of first officer £140 per annum, and second £120 per annum.
HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, board, and washing.
HEREFORDSHIRE COUNTY COUNCIL.—Assistant Medical Officer of Health. Salary £250 per annum.
HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.
KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, apartments, laundry, &c.
KENT EDUCATION COMMITTEE.—Medical Inspector of School Children. Salary £250 per annum.
KIRKMABRECK PARISH.—Medical Officer. Salary £40 per annum.
LAMBETH, PARISH OF.—Chief Medical Officer. Salary £500 per annum, with furnished house, and allowance of coals, gas, and water.
LONDON COUNTY OF.—Twenty-eight Assistant School Doctors in Public Health Department of London County Council. Salary £120 per annum.
LONDON LOCK HOSPITAL.—House Surgeon and Assistant House Surgeon to Female Hospital. Salary £100 and £80 per annum respectively, with board, lodging, and washing. Also House Surgeon to Male Hospital. Salary £100 per annum, with board, lodging, and washing.
LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £105 per annum.
PUBLIC DISPENSARY, 122, Drury lane, W.C.—Resident Medical Officer. Salary £105 per annum, with apartments.
ROBERT BROWNING SETTLEMENT, Walworth, S.E.—Honorary Superintendent.
ROYAL HOSPITAL OF BETHLEM, Lambeth-road, S.E.—Resident Physician and Medical Superintendent. Salary £750 per annum.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—Assistant House Surgeon for six months. Salary £20, with luncheon and tea.
ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Honorary Anæsthetist.
SALFORD COUNTY BOROUGH FEVER HOSPITAL.—Assistant Medical Officer. Salary £150 per annum, with apartments and board.
SALFORD ROYAL HOSPITAL.—Honorary Assistant Surgeon.
SHEFFIELD CHILDREN'S HOSPITAL, EAST END BRANCH.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.
SHEFFIELD UNION HOSPITAL.—Resident Assistant Medical Officer, unmarried. Salary £100 per annum, with apartments, rations, &c.
SOUTH UIST.—Medical Officer. Salary £100, with house.
STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.
STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.
STOCKTON-ON-TEES, STOCKTON AND THORNABY HOSPITAL.—House Surgeon, unmarried. Salary £180 per annum, with residence, board, and washing.
STOKE-ON-TRENT, COUNTY BOROUGH OF.—Medical Officer (female). Salary £250 per annum.
STROUD GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.
THROAT HOSPITAL, Golden-square, W.—Resident House Surgeon. Salary £75 per annum, with board, residence, and laundry.
UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Resident Medical Officer.
UNIVERSITY OF LONDON.—Examiners.
WARMINSTER UNION, Wilts.—District Medical Officer and Public Vaccinator. Salary £90 per annum.
WEST HAM AND EAST LONDON HOSPITAL, Stratford, E.—Two Honorary Physicians and Three Honorary Surgeons. Also House Surgeon. Salary £100 per annum, with board and rooms.
WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Physician. Also Honorary Medical Registrar. Also House Physician for six months. Board, lodging, and laundry allowance provided.
WESTMINSTER HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board and residence.
WINDSOR, KING EDWARD VII. HOSPITAL AND DISPENSARY FOR WINDSOR, ETON, AND DISTRICT.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, laundry, &c.
YORK COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with board, residence, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Twyford, in the county of Berks.

Births, Marriages, and Deaths.

BIRTHS.

BOUSFIELD.—On Nov. 15th, at Princes-square, W., the wife of Stanley Bousfield, M.D., of a son.
BRAINE-HARTNELL.—On Nov. 12th, at Weston House, Cheltenham, the wife of Christopher Braine-Hartnell, F.R.C.S. Edin., of a son.
DANIEL.—On Nov. 14th, at Upper Wimpole-street, W., the wife of Peter Daniel, F.R.C.S., of a son.
THOMSON.—On Nov. 7th, at Blenheim-place, Edinburgh, the wife of H. Torrance Thomson, M.D., of a son.
YOUNG.—On Nov. 8th, at Camden-crescent, Dover, the wife of Dr. Francis Percy Young, of a daughter.

MARRIAGES.

COPE—NORTON.—On Nov. 9th, at St. Mark's, Brighton, Ricardo Cope, M.R.C.S., to Ethel Amy, youngest daughter of the late George Norton and of Mrs. Norton.
HAY—BECK.—On Nov. 12th, at St. Augustine's, Broxbourne, Herts, Kenneth Robert Hay, M.B., to Rachel, second daughter of Mr. and Mrs. Ernest Beck.
MACKENZIE—KENNEDY.—On Nov. 16th, at St. Luke's, Nightingale-lane, S.W., by the Right Rev. Bishop Welldon, the Rev. Canon Clarke, and the Rev. B. Dulley, Stephen Morton Mackenzie, M.A., M.B., B.C., of Rose Hill, Dorking, eldest son of the late Sir Stephen Mackenzie, M.D., of Cavendish-square, to Edith Madeline, eldest daughter of the late Arthur Kennedy of 4, Clement's Inn and Epsom.
WATSON—FITHIAN.—On Nov. 11th, 1910, at the Marshall-street Presbyterian Church, Portland, Oregon, U.S.A., by the Rev. Charles Hays, D.D., William Bertram Watson, M.D. Lond., of Harrogate, son of the late John Watson of Stockton-on-Tees, and Mrs. Watson of Ilkley, to Pauline Chapman, only daughter of Mr. and Mrs. O. H. Fithian of Portland, Oregon, U.S.A.

DEATHS.

CAVERHILL.—On Nov. 4th, at Jedneuk, Jedburgh, the residence of his brother, Thomas Francis Spittal Caverhill, F.R.C.P. Edin.
TOOVEY.—On Nov. 6th, at Jebba, Southern Nigeria, Thomas Edward Fraser Toovey, F.R.C.S. Edin., West African Medical Staff, aged 43.
TURKHUD.—On Oct. 15th, at Bombay, India, from enteric fever, Violet Ackroyd Turkhud, M.D., B.S. Lond.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DETECTION OF WORM-EATEN DRUGS.

A CONTRIBUTION to the literature concerning the examination of drugs was made by Professor H. G. Greenish in a paper read at this month's evening meeting of the Pharmaceutical Society. It is not a difficult matter to distinguish sound from worm-eaten drugs when the samples examined are in the crude state, but hitherto no satisfactory method has been suggested for detecting powdered drugs prepared from drugs which have been attacked by insects. Professor Greenish and Miss D. M. Braithwaite, however, have been investigating the subject, and in the paper referred to describe a method by which the presence of minute traces of the drug-room beetle (*Sitodrepa panicea*) in powdered drugs can be shown. This little insect belongs to the family of which the various members are to be found in old houses, furniture, and palings, in collections of dried plants, in biscuits, and in many other substances. The quantity of mature beetle present in an infested drug is so small that its detection by direct examination under the microscope is practically impossible, and some other method had therefore to be devised. This consists in destroying the organic matter of the powdered drug by a process which leaves nothing but sand and particles of beetle which are separated by centrifugation, washed, and mounted. The particles of beetle are then readily detected under the microscope by their conspicuous brown colour, and most of them exhibit either hairs or the scars of hairs. By this means it is possible to detect so small a quantity as 0·00001 gramme of beetle in 5 grammes of powdered drug. Professor Greenish and Miss Braithwaite have examined a number of specimens of powdered drugs and spices and have found particles of beetle in ginger, nutmegs, coriander, dandelion root, ergot, and belladonna root and leaves. So ubiquitous is the pest that considerable discretion must be exercised before condemning a powder in which traces only of it can be detected. At the same time Professor Greenish and Miss Braithwaite express the opinion that although its presence does not appear to be injurious to health, it seems obvious that powders prepared from worm-eaten spices or drugs should not be offered for sale to the prejudice of the purchaser, or in undue competition with those prepared from sound materials.

"SCIENCE AND SINGING."

To the Editor of THE LANCET.

SIR,—Had your reviewer been more up to date in the matter under consideration the reading of my book would not have given him such a violent shock, for he would have known that in November last year (that is two months after the publication of "Science and Singing") Dr. Marage of Paris presented to the Académie des Sciences an account of his laryngological experiments, and he stated therein that he had come to the conclusion that the vocal cords do not in themselves produce sounds. Further, I have before me as I write a copy of *Le Bulletin Médical* (of Paris) of April 17th, 1887, wherein mention is made by medical men of different cases where patients have both talked and sung after the extirpation of the vocal cords.

Letters from medical men bearing testimony to the practical value of my work can be seen in the *Musical Standard* of Jan. 15th and 22nd of this year. I will close with an extract from a French review of my book just to hand: "Les esprits superficiels n'y verront qu'une hérésie de plus en la matière; mais je n'hésite pas à penser que ceux qui le liront attentivement se laisseront convaincre, et sauront gré à l'auteur d'avoir en assez d'indépendance pour exposer ses propres idées."

I am, Sir, yours faithfully,

Broadwood's Studios, Conduit-street, W., Oct. 21st, 1910. ERNEST G. WHITE.

*** We cannot accept Mr. White's physiology, though it has, in his opinion, been supported by Dr. Marage; we should be interested to hear Dr. Marage's views on Mr. White's book.—ED. L.

CONFERENCE ON CHOCOLATE AND COCOA.

AT the International Food Congress which was held in Paris in 1909 there were many discussions on the subject of what should constitute purity in cocoa and chocolates, but the findings of the Congress were not universally accepted. A desire has arisen for a special Congress in connexion with the subject, and it has been arranged that such should take place in Paris in January, 1911, when there will be present delegates from Germany, England, Austria-Hungary, Belgium, Brazil, Spain, the United States, France, Holland, Italy, Mexico, and Switzerland. The Congress will be limited to five representatives from each nation, and each nation will only have the right to one vote. The Congress is being arranged under the auspices of the White Cross Society of Geneva, whose delegate in the United Kingdom is Mr. Loudon M. Douglas, F.R.S.E., of 3, Lauder-road, Edinburgh.

THE ALLEGED SPECIFIC ORGANISM OF YELLOW FEVER.

To the Editor of THE LANCET.

SIR,—You will greatly oblige me by stating what was really the so-called *Micrococcus tetragenus fevre flava*, discovered by Dr. Carlos I. Finlay, of this capital city of Cuba, as the germ of yellow fever. I have a vague remembrance that Dr. George M. Sternberg made a thorough study of that discovery.

I am, Sir, yours faithfully,

A. M. FERNANDEZ DE YBARRA, M.D., Lately of New York City.

Havana, Cuba, Oct. 24th, 1910.

*** The organism which Dr. C. Finlay of Havana claimed to have identified as the specific microbe of yellow fever was carefully investigated on behalf of the United States Government by Dr. G. M. Sternberg, who reported adversely of Dr. Finlay's discovery. This same expert also investigated the contention of several other discoverers who put forward certain other microbes, each as the true cause of yellow fever, but equally with unfavourable results. The germ of the disease has not been discovered beyond dispute; and authorities are fairly well agreed that it almost certainly is not a bacterium but a protozoon, ultra-microscopic and therefore not recognisable with our present means. The Micrococcus tetragenus, as known to bacteriologists at the present time, is often found in suppuration in the region of the mouth or neck, and it also occurs in the lungs. It probably has a pyogenic action in the human subject. It is often found associated with other micro-organisms. When injected into mice it causes septicæmia. Cases of pyæmia in man have been reported where the M. tetragenus was found in pure culture.—ED. L.

THE DESTRUCTION OF FLEAS.

To the Editor of THE LANCET.

SIR,—In answer to "Medicus," I give my experience. During residence in a workhouse infirmary, which involved frequent visits to the receiving ward, I kept drops of eucalyptus oil on (*a*) ankles, (*b*) wrists, and (*c*) neck, with successful results. I also carried a chloroform drop-bottle for emergencies. At another time, being resident in a hospital, and my bed being infested with pulices, I emptied one ounce of eucalyptus oil on the mattress. Cats and padded chairs have been treated successfully in the same way. The practice of fixing bags of camphor on the bottoms of the trousers is of comparatively little use. As for the destruction of fleas, dust is proved to be favourable, if not necessary, for their morphological changes. According to the "Cambridge Natural History," the Pulex irritans breeds freely in an uninhabited apartment. The larva of the Pulex serraticeps (cat and dog flea) has been reared on the sweepings of an ordinary room. The development of a generation of the serraticeps appears to be two or three weeks.

I am, Sir, yours faithfully,

Nov. 12th, 1910. FLEBILIS OCCIDIT.

A SUGGESTION FOR TREATMENT OF ARTHRITIS OF THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—In reply to "M.D." (THE LANCET, Nov. 5th, p. 1392), I may say that his best plan would be to attack his arthritis vigorously at once. For this purpose there is nothing more certain than the method recommended by Dr. P. W. Latham and practised by myself with gratifying success (see THE LANCET, April 6th, 1901, and Sept. 7th, 14th, and 28th, 1907).

I am, Sir, yours faithfully,

Bournemouth, Nov. 10th, 1910. W. J. MIDELTON.

PURE TOBACCO.

To the Editor of THE LANCET.

SIR,—Your readers might wisely try the following. Get leave from the Excise authorities to buy a pound or more of real good leaf tobacco from any good manufacturer, and then find a good A.B. in the Royal Navy and get him to do the "baccy" up in "perique" fashion, as used in the Navy. I have used it for years, and you certainly get the real tobacco flavour. I sometimes think a little additional flavour would be advantageous—I am now smoking some Havanna leaf done up in perique fashion—and certainly most of the "mixtures" now sold are atrociously adulterated, though they have the "flavour" and so are pleasant smoking.

I am, Sir, yours faithfully,

Nov. 15th, 1910. HOLLINS CROSS.

THE BLIND SOCIAL AID SOCIETY.

To the Editor of THE LANCET.

SIR,—The Blind Social Aid Society hopes that you will be good enough to assist them in their endeavours for the welfare of the blind by inserting this letter in your columns. We wish to bring to public notice the excellent qualifications and abilities of the properly educated blind in their various professions and trades, musicians, tuners, brush, basket, mat makers, &c., to the end that they may have the assistance of the many persons who would gladly give them employment if they but knew of them. We propose to give a series of local concerts round London, by which we hope successfully to advertise the blind working in the various districts, and shall be pleased to hear from Church

secretaries and others having halls seating 200 or more who would like us to come and give them a first-rate concert. By the coöperation of the Churches and ourselves we hope to secure good audiences and also more employment for those who, though so heavily handicapped, are thoroughly well qualified and anxious to become self-supporting.

Replies will be gladly received by the honorary secretary.

5, Minories, London, E.C. ALFRED CARR.

SUPERSTITIOUS REMEDIES.

To the Editor of THE LANCET.

SIR,—In the *Standard* of yesterday (Nov. 11th) there is a paragraph quoted from THE LANCET about a superstitious cure for shingles, &c. It struck me as a strange coincidence that the Welsh name for shingles is "eryrod" = eagles. I wonder how that came about?

Trusting this may be of interest to your readers,

I am, Sir, yours faithfully,

Aberystwyth, Nov. 12th, 1910. (Miss) SUSAN WILLIAMS.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Nov. 11th-19th (London).—Stanley Exhibition.

In 1911:—

Feb. 20th-25th (Cairo).—Fifth International Congress for the Blind.

March 2nd-6th (Berlin).—Thirty-second Balneological Congress.

April 4th-7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.

May-October (Dresden).—International Hygiene Exhibition.

May-October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)

May-October (?) (London, Shepherd's Bush).—Coronation Exhibition.

June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.

July (Birmingham).—British Medical Association.

August or September (Berlin).—Third International Laryngo-Rhinological Congress.

September (Brussels).—Exhibition of Fractures.

Sept. 11th-16th (The Hague).—Thirteenth International Congress on Alcoholism.

,, 18th-23rd (Sydney).—Australasian Medical Congress.

,, 24th-30th (Rome).—International Congress on Tuberculosis.

,, 25th-29th (Rome) Seventh International Congress of Dermatology and Syphilology.

October (Cologne).—International Congress of Criminal Anthropology.

In 1912:—

July (?) (Cologne).—International Congress of Nurses.

September (Prague).—International Congress of Radiology and Medical Electrology.

September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.

In 1913:—

(London).—Seventeenth International Congress of Medicine.

In 1915:—

(London).—International Prison Congress.

(London).—Imperial Exhibition (?)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—A. F. Voelcker, Sir John F. H. Broadbent, Bart.): at 5.30 P.M.

Paper:

Dr. F. Craven Moore and Dr. L. Kilroe: The Use of Belladonna in Dyspepsia.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—J. P. Lockhart Mummery, T. R. Whipham, G. S. Haynes) at 11, Chandos-street, W.: at 4.30 P.M.

Cases and Specimens.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Paper:

Dr. J. Edward Squire, C.B.: Some Points in Relation to Tuberculosis and its Prevention.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY.—8 P.M., Mr. C. R. Darling: Industrial Pyrometry. (Lecture I.)

WEDNESDAY.—8 P.M., Sir Henry H. Cunynghame: Methods of Detecting Fire Damp in Mines.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Mr. J. E. R. McDonagh: Treatment of Syphilis by "606," with demonstration of illustrative cases.—Mr. R. Warren: Punctured Wounds of the Heart.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. G. Adamson: Clinique (Skin). 5.15 P.M., Lecture:—Mr. T. C. English: Diagnosis and Treatment of Chronic Intestinal Obstruction.

TUESDAY.—4 P.M., Dr. C. T. Williams: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. L. Bunch: Some Methods of Treating Skin Diseases.

WEDNESDAY.—4 P.M, Mr. T. P. Legg: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. A. Latham: The Administration and Value of Tuberculin in Various Forms of Tuberculosis.

THURSDAY.—4 P.M., Dr. E. Cautley: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. Latham: The Administration and Value of Tuberculin in Various Forms of Tuberculosis.

FRIDAY.—4 P.M., Mr. W. Stuart-Low: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Edwards: Urinary Surgery.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: The Prevention of Tropical Diseases.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. R. H. Cole: The Modern Treatment of the Insane.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Mr. Dunn: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. Carling: Operative Treatment of Fractures.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. McGavin: Operative Dangers in General Practice.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. H. Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie). 4.30 P.M., Lecture-Demonstration:—Dr. A. H. Pirie: The Value of X Rays in the Early Diagnosis of Diseases of the Chest.

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Demonstration:—Dr. G. P. Chappel: Selected Medical Cases.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. H. Evans); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

MONDAY.—5.15 P.M., Demonstration:—Dr. J. H. Thursfield: Food and Food Diseases—Rickets. (Special Post-Graduate Course.)

TUESDAY.—5.15 P.M., Demonstration:—Mr. H. A. T. Fairbank: Deformities—Deformities associated with Rickets, Dislocation of Patella. (Special Post-Graduate Course.)

WEDNESDAY.—5.15 P.M., Demonstration:—Dr. J. H. Thursfield: Food and Food Diseases—Infantile Scurvy. (Special Post-Graduate Course)
THURSDAY.—4 P.M., Lecture:—Mr. Waugh: Swellings in the Inguinal and Scrotal Regions.
FRIDAY.—5.15 P.M., Demonstration: Mr. H. A. T. Fairbank: Deformities—Scoliosis, Lordosis, Kyphosis, Neurotic Spine. (Special Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.
WEDNESDAY.—4 P.M., Lecture:—Dr. Bosanquet: Theory and Practice in the Treatment of Pulmonary Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.
TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. A. Turner: Peripheral Neuritis.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Stewart: Syphilitic Compression Paraplegia.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.
TUESDAY.—3.45 P.M., Lecture:—Dr. Kingsford: Anæsthetics.
FRIDAY.—3.45 P.M., Mr. W. Wallis: Mouth and Teeth.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.
THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Tuberculosis of the Skin—I., Lupus Vulgaris; II., Tuberculosis Verrucosa Cutis; III., Scrofuloderma.

ANCOATS HOSPITAL, Manchester.
THURSDAY.—4.15 P.M., Mr. G. Wright: Head Injuries. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (23rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan 9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (24th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY 25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (26th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Observations ON THROMBOTIC SOFTENING OF THE SPINAL CORD AS A CAUSE OF SO-CALLED "ACUTE MYELITIS."

By H. CHARLTON BASTIAN, M.D. Lond., F.R.S.,

CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

Discrepancy of Views on Pathogenesis.

THERE seems little room for doubt that the common "softenings" met with in the spinal cord are in all essential respects similar to the common "softenings" met with in the brain. It is now generally acknowledged that these latter softenings are due to vascular occlusions (embolism and thrombosis), cutting off the blood-supply from the affected region of the brain, and thereby leading to degenerative processes in the sites supplied by the occluded vessels.

There is absolutely no reason for supposing that inflammation should be more common in the spinal cord than in the brain, nor that the process which causes the great majority of softenings of the brain (simple vascular occlusions) should not be capable of producing analogous results in the spinal cord. Yet works on medicine at the present day and for some time past would have us believe that while the common softenings of the brain are results of non-inflammatory degenerations, those of the spinal cord are due to inflammation. What explanation can be given for this seemingly unwarrantable discrepancy?

The main cause for the persistence of this anomalous point of view is undoubtedly to be found in the fact that while embolism and thrombosis are both common in the brain and comparatively easy to detect in its great vessels, embolism is so rare as to be almost non-existent in the spinal cord, while thrombosis is exceedingly difficult to detect because of the comparatively minute vessels that supply this section of the nervous system. This, I say, is the main cause for the persistence of what some deem to be an erroneous point of view;[1] but another cause was originally operative in this country in initiating the view that the pathogenesis of softenings of the brain, as commonly met with, is altogether different from the pathogenesis of common softenings in the spinal cord.

This initiatory cause had the following origin. Previous to 1866 in this country softenings of the brain were commonly regarded as of inflammatory origin, though during the few preceding years evidence had been accumulating, especially through the labours of certain French pathologists, which ultimately tended to show in the most conclusive manner that such softenings were degenerative in nature and resulted from simple vascular occlusions. When Dr. (afterwards Sir J.) Russell Reynolds commenced in 1865 his great *System of Medicine*, which was for so long an authoritative work not only in this country but abroad, he did me the honour of asking me to write the sections on pathology for various diseases of the brain, of which he was to give an account in that work. In the letter that he subsequently wrote to me he assigned for these sections a large number of pages for an article on "Cerebritis" and only one or two pages for that on "Non-inflammatory Softening." I accepted his proposals on condition that these numbers should be reversed, as I had much to say concerning the latter process and very little indeed concerning the former. But while Dr. Reynolds agreed to my point of view and shaped his own articles in accordance therewith (as may be seen by reference to that work), so that the pathology of the brain was dealt with from the newer point of view then first introduced from France, he, as a too indulgent editor, actually allowed Dr. Radcliffe to deal with the corresponding affections of the spinal cord from the old point of view. Thus, in this then very authoritative work such processes as were described as non-inflammatory degenerations of the brain were in the spinal cord said to be of inflammatory origin, and what I felt sure would happen has happened—that is, the anomalous point of view has proved very persistent.

The opportunity for expressing my own views concerning "softenings" in the spinal cord came after I had carefully looked into this matter for several years from the pathological as well as from the clinical point of view, when I was asked by the late Sir Richard Quain to write a number of articles on diseases of the spinal cord for his *Dictionary of Medicine*. This I undertook to do, and in the first edition of that work, published in 1882, the first statement appeared of the views which I held, and have continued to hold, as to the altogether excessive rôle attributed to inflammation, not only in acute but also in chronic diseases of the spinal cord. The statement of these doctrines was repeated in 1886 in my work entitled *Paralyses, Cerebral, Bulbar, and Spinal*, and also in two subsequent editions of Quain's *Dictionary* (1894 and 1902). Owing to the fact of the different editions of the *Dictionary* it will be more convenient for reference if I make some citations from the work published in 1886. Referring in that work to what is commonly known as "Myelitis" the following passage occurs (p. 583):—

> By many writers and practitioners the term "myelitis" is used in a somewhat vague manner, and with an evident tendency to include under it as many different affections or states of the spinal cord as possible. Critical discrimination seems to have been, and still seems to be, somewhat in abeyance by many who describe or report cases of disease of the spinal cord. They set down, only too frequently, as instances of "myelitis" not only all cases in which the substance of the spinal cord is softened, but still more all those in which it is indurated—and at times, no less impartially, those in which it is merely degenerated.

This passage was followed by statements in illustration of these various usages of the terms Acute and Chronic Myelitis. On a previous page my own views as to the limitations which should be ascribed to the inflammatory process in the spinal cord were thus stated (p. 552):—

> The writer is far from denying that a primary inflammation may involve areas of the cord, and entail "softening" of its substance. He believes, however, that "acute myelitis" is far more likely to occur as a secondary process, in connexion with pressure upon, and consequent irritation of, some part of the cord encroached upon by fractures and dislocations of the vertebræ, or when otherwise wounded; also as an occasional sequela either of scrofulous pachymeningitis, or of the direct pressure made upon the cord by some meningeal tumour, or of hæmorrhage into its substance. Yet he is far from believing that *all* the secondary softenings met with in the spinal cord are necessarily of inflammatory origin. Many of these, also, are due to degenerative rather than to inflammatory processes.
>
> Processes of degenerative softening are mostly brought about quickly, and they would, in the main, correspond with what is commonly spoken of as "acute myelitis." As for "chronic myelitis" (in the commonly understood sense of chronic softening) the writer believes that no such disease should be any longer described. Many "softenings" are, in a certain sense, chronic, as, though they may be more or less abrupt in their onset, they tend to last long, rather than to kill quickly. Again, other maladies which the older physicians would have ascribed to "chronic myelitis" or "chronic softening," are now known to partake more of the nature of chronic indurations, and to have as their basis processes of sclerosis.

My views on this subject have met with only a very partial acceptance in this country, as may be gathered from the fact that in the last edition but one of the *Nomenclature of Diseases*, issued by the Royal College of Physicians of London, and probably also in the latest edition, as well as in Sir Clifford Allbutt's celebrated new *System of Medicine* (Vol. VII., 1899), there is no mention of Softening of the Spinal Cord other than such as is assumed to be due to Inflammation.

Still, there have been some notable converts both in this country and abroad.[2] The first person in this country to express accord was Dr. R. T. Williamson[3] (1894–95) in an important communication "On the Relation of Spinal Diseases to the Distribution and Lesions of Blood-vessels of the Spinal Cord." Then came a paper by Dr. Douglas Singer (1902) on "The Pathology of so-called Acute Myelitis,"[4] in which a brief historical summary to that date will be found; while in 1904[5] there is a paper by Dr. F. E. Batten on "The Pathology of Acute Poliomyelitis," in which he disputes the rôle of inflammation in that disease, as Dr. Williamson had previously done for some of the cases at least. Finally, Dr.

[1] A contributory cause is due to the fact that such affections of the spinal cord are, as a rule, much less speedily fatal than the corresponding affections of the brain, while to ascertain from post-mortem evidence the true pathology of the spinal cord affection an examination ought to be made within three or four weeks from the onset of the malady.

[2] On the continent Pierre Marie, Bruns, Ziegler, Oppenheim, and others adopt the view that the majority of cases of so-called acute myelitis are due to thrombosis.

J. S. Risien Russell in his Harveian lecture for 1907[6] gives the most thorough support to my views both in regard to so-called Acute Myelitis and also Chronic Myelitis. After referring to the frequency with which in hospital and private practice, as well as in text-books on Medicine and on Diseases of the Spinal Cord, one meets with references to "Myelitis," he says:—

> However, I venture to affirm that myelitis, if the term be strictly applied to an inflammation of the spinal cord, is in reality a rare malady, and that much of what is spoken of under this name is in reality a softening of the spinal cord consequent on vascular occlusion, in which inflammation plays no part, except it be that some inflammatory process in connexion with the walls of the blood-vessels permits of the thrombosis or clotting which results in the softening.

The communications that I have just referred to may fairly be taken as indications that the newer views are at last gaining ground, and that more persons are beginning definitely to recognise that the cause which is supreme in the production of Softening of the Brain is no less supreme in the production of similar changes in the Spinal Cord. So many still adhere, however, to the old point of view that it seems important to repeat, with the additional evidence that is now available, the principal reasons for the belief that what is commonly known as "acute myelitis" is in reality a degenerative softening resulting from vascular occlusion.

We must look at the problem from the point of view of Etiology and Pathogenesis, as well as from that of Symptomatology.

ETIOLOGY AND PATHOGENESIS.

It is well known that so-called Acute Myelitis is met with principally among one or other of three classes of patients—namely, (1) elderly persons with degenerated vessels and, often, failing heart power; (2) young or middle-aged adults suffering from syphilis; and (3) children or adults when actually suffering from other infectious diseases, or during periods of convalescence therefrom.

In the first of these categories we have the two best known and most potential causes favouring thrombosis; in the second we have to do with a fertile cause of thickening of the external and middle coats of the arteries and of endarteritis, alike in the brain and in the spinal cord, such as lead on to thrombosis; while in the third category, in which acute myelitis is less common than in the other two, we have to do with blood changes and toxins, often associated with feeble cardiac action, which may well act as causes of thrombosis in vessels of the spinal cord as well as of other regions. In these infective conditions toxins may excite endarteritis in the small vessels, while, in addition, alterations in the character of the blood may also occur of a kind to favour the occurrence of thrombosis, as in convalescence from typhoid and other fevers, and after parturition.

Thus the conditions and states of the system in which so-called Acute Myelitis is most prone to occur are found to be those that would especially favour the occurrence of the process of thrombosis, and this is the kind of occlusion that almost solely occurs in spinal vessels. There are, in fact, good anatomical reasons why embolism should be rare in the spinal cord, and why thrombosis should be especially prone to occur in the vessels of this part of the nervous system.

In regard to embolism, as I previously pointed out[7]: "Emboli reach the brain much more rarely by way of the vertebrals than by way of the carotids; and the principal arteries of the spinal cord are either direct off-sets from the vertebral (anterior spinal) or indirect branches from the same (posterior spinal). Apart from these vessels the blood-supply of the cord comes from smaller twigs (still less likely to convey embolic particles), derived principally from the intercostal and lumbar arteries." Even when embolism does occur, "it can only be in very small vessels, whose occlusion would merely give rise to minute foci of softening not capable of causing any distinct paralytic condition."

On the other hand, the special nature of the distribution of vessels in the spinal cord is such as directly to favour the occurrence of thrombosis, as was originally pointed out by Moxon,[8] and especially of thrombosis in the lumbar region, where so-called Acute Myelitis is so frequently met with. Moxon dwelt upon the great length of the very slender spinal arteries, for, as he said, "no arteries so small as these run so great a length elsewhere in the body," so that it becomes necessary to supplement their blood-supply wherever possible, and advantage is taken of the nerve roots on which to send up little reinforcing arteries. These run a comparatively short course throughout the greater part of the spinal cord, but as we approach its lower extremity, where the blood-supply from above has to be furnished with greater difficulty, the much longer length of the nerve roots entails also a correspondingly longer course for the very slender reinforcing vessels. It can be easily understood, therefore, that the circulation is more easily impeded in this than in other regions of the spinal cord when local or general causes favouring thrombosis are in operation.

Then, again, thrombosis may also take place in the peculiarly tortuous network of veins which surrounds the spinal cord on all sides. Ollivier long ago called attention to the probably natural slowness of the blood current through these vessels, and added that he had often seen in elderly persons fibrinous clots filling the veins of the cord as well as those that accompany its nerve roots.

We have thus the nature of the vascular supply of the cord favouring thrombosis, and favouring it especially in that region of the organ in which so-called acute myelitis is known to be most common.

Again, we have the disease presenting itself especially in persons and under conditions in which the occurrence of such a process is known to be favoured, and when there is no reason whatever for supposing that a primary inflammatory process should have been set up in the spinal cord.

Lastly, if we turn to the actual morbid anatomy of the lesions in the majority of cases of so-called Acute Myelitis in which an early examination has been possible we meet with an absence of the distinctive signs of inflammation (that is, small-celled infiltration of the tissues around the vessels and collections of pus). This may be gathered even from the writings of many of those who describe the disease as being caused by inflammation. The distinctive signs of inflammation are absent from their description of the morbid changes, and what we do find is a description of the existence of a state of things exactly comparable with what is to be met with in a focus of softening of the brain known to be merely degenerative, and caused by thrombosis of the middle cerebral artery or one of its branches. Many cases have now been described in which, notwithstanding the difficulty entailed by the small size of the spinal arteries, the actual thrombosed vessels have been discovered in the foci of softening. Thus Professor D. J. Hamilton, many years ago, in a case of pyelitis in which blood poisoning was supposed to have existed, found multitudes of minute thrombi in the vessels of the spinal cord, though it was not ascertained that they were associated with micrococci.[9] Other cases have been recorded by Williamson, Singer, and Batten,[10] in which occluded and gorged vessels, with small-cell infiltration of their sheaths and minute hæmorrhages were found—just such as were produced by Prevost and Cotard when they occluded spinal arteries by the injection of tobacco seeds. These first stages of change are soon followed by degeneration with disintegration of the myeline of the nerve tubes, and the appearance of multitudes of the well-known "granulation corpuscles."

Turning now to what is said in text-books concerning the Etiology of primary Acute Myelitis by those who regard it as an inflammatory affection, we find them admitting that in a considerable number of cases no cause can be assigned for the origin of such an inflammation, while mention is made of two or three assumed causes—such as suppressed menstruation, sexual excesses, or muscular strain—whose causative potency for the excitement of an inflammation of the spinal cord may well be doubted when one thinks of the overwhelming number of cases in which such assumed causes are operative without leading to the effect in question.

As to the other causes that are cited, one of them—namely, exposure to wet and cold—is just as likely (by lowering the circulation in persons otherwise predisposed) to be a cause of thrombosis in some of the spinal vessels as of

[6] THE LANCET, vol. ii., p. 1.

[10] See Williamson (loc. cit., p. 328, and also in his work "Diseases of the Spinal Cord," 1908, p. 392, Plates v. and vi., and Figs. 175 and 176), together with the communications of Douglas Singer and F. E. Batten

an inflammation; while the remaining causes—namely, (1) the co-existence or immediate precedence of some infectious disease; (2) syphilis; and (3) the occupation of a diver—are far more likely to favour the occurrence of thrombosis than of inflammation of the spinal cord. To the first and second of these causes as provocative of endarteritis and arteritis I have already referred, while as to caisson disease, which is cited by Dr. F. Taylor[11] as a condition causing Acute Myelitis, we may well ask why inflammation of the cord should occur in such a condition, and whether it is not much more probable that the trouble has been caused by the well-known liberation of air-bubbles occluding the small vessels of the cord.

SYMPTOMATOLOGY.

The onset of so-called Acute Myelitis is usually more or less sudden. It commences by certain local symptoms, such as numbness and weakness of limbs, soon developing into actual motor paralysis with more or less of impaired sensibility, while there may be little or no elevation of temperature or other febrile symptoms.

This is admitted by those who believe the disease to be actually caused by inflammation. Thus Dr. F. Taylor, who follows in the new *System of Medicine* the line adopted by Dr. Radcliffe in the old *System*, says: "The symptoms may be divided into the purely local and the more general. The local symptoms, those, that is, that depend on disturbance of the functions of the spinal cord, are the most important." So much is this the case in his estimation that Taylor begins by reference to these local symptoms, and actually says nothing about the general symptoms,[12] though subsequently, when describing one particular form of myelitis, he does say (p. 19) that "in the early days of an acute myelitis there may be a slight degree of fever, with the usual accompaniments." Other writers also dwell upon the importance and first appearance of local symptoms, and admit that general symptoms are in a considerable number of cases altogether absent.

This symptomatology is quite in accordance with the onset of the disease as a result of some local change leading to the occlusion of vessels in the affected region of the spinal cord; but in the cases where the malady is actually caused by inflammation we have every right to expect that, as with inflammation of other organs, there would be an important assemblage of general symptoms, such as malaise, shivering, headache, depression, loss of appetite, pyrexia—symptoms which, as we have seen, are notably absent in the majority of cases of so-called Acute Myelitis.

ACUTE POLIOMYELITIS.

The pathology of this disease has been much discussed of recent years, and I do not propose to dwell upon it at any length.

Even as far back as 1882, and again in 1886, I pointed out the improbability of an inflammation limiting itself to the anterior horns in the way that the morbid changes are limited in this disease. Thus in *Paralyses, Cerebral, Bulbar, and Spinal*, p. 555, the following passages occur:—

> But in two or three distinct diseases the ganglion cells of the anterior cornua in different parts of the cord are prone to be suddenly overtaken by an etiologically obscure and altogether inexplicable failure of nutrition, which speedily entails an atrophy of the particular cells affected. This, for instance, occurs as the anatomical basis of "acute spinal paralysis" both as it presents itself in children and (though more rarely) in adults; it is met with also in "chronic spinal paralysis." In these diseases whole groups of contiguous and functionally related cells are affected simultaneously, and as the atrophy progresses there is generally evidence of a secondary overgrowth of the neuroglia surrounding such nerve cells in the anterior cornua.
>
> Of late some more evidence has been forthcoming to show that this process may be at first inflammatory in type, so that the terms "cornual myelitis," or "anterior poliomyelitis," which have also been applied to these affections, are more in accordance with known facts than was formerly the case. Still, it may be said that inflammation does not usually limit itself to individual tissue elements, and the slight overgrowth of the contiguous neuroglia may well be a secondary simple hyperplasic process. This latter process is, indeed, less evident where, as in "progressive muscular atrophy," the initial and mysterious atrophy of individual ganglion cells occurs more slowly and more sparsely.

Several years later (1894–95) Dr. R. T. Williamson, as we have seen, laid stress upon the fact of the limitation of the morbid changes in acute poliomyelitis to the regions supplied by the anterior median arteries and their branches, and referred to the often sudden onset of the disease as being "too sudden for primary inflammation," and hence as "very suggestive of thrombosis," when hæmorrhage can be excluded; and he recorded a case of this kind in which no trace of hæmorrhage was found in any part of the cord.

Then in 1904 F. E. Batten[13] also favoured the view that the disease is caused by thrombosis or embolism of some of the small vessels supplying the anterior cornua, and recorded three cases in support of his views, though Head and Campbell[14] adhere to the notion that the changes met with in the disease are of an inflammatory nature.

Starr, again, considers that the cases in which there are no febrile symptoms at the onset may be due to hæmorrhage or thrombosis; or else that "the lesion is a primary degeneration of nerve cells," as I suggested in 1882. The view was also taken by Charcot and V. Kahlden that in certain cases the initial change is an acute degeneration limited to certain nerve cells in the anterior horns. And as Williamson points out,[15] it must be admitted that in many old cases in which the morbid anatomy has been investigated "interstitial changes have been very slight in comparison with the marked changes in the nerve cells."

Thus it seems evident that there is very much evidence against the view that inflammation is at all a common cause of so-called Acute Poliomyelitis, whether we look at the evidence from the point of view of the nature and limitation of the morbid changes, or from the point of view of the often sudden onset of the disease with either complete absence or the presence of only very slight febrile symptoms. Still, as in the more general affection, so here there is no reason to deny that inflammation *may* at times be a cause, while admitting that either vascular occlusions or acute primary degenerations of the very specialised ganglion cells will suffice to account for the great majority of cases.

This latter conclusion is in no way invalidated by the fact that an epidemic prevalence of the disease—strongly suggestive of an infectious origin, as Williamson[16] and Farquhar Buzzard[17] have pointed out—sometimes occurs; since, as Batten says, liability to thrombosis after acute specific infections is well known and due to morbid changes in blood. And then, again, the irritation of vessel walls induced by the presence of toxins in these affections might, in other cases, undermine the nutrition of the great ganglion cells. I quite agree with Batten also when he urges that such changes in blood and vessel "walls," productive of so-called Acute Poliomyelitis, may be occasioned "by various and totally different forms of infection," rather than by some "special specific infection."

CONCLUSION.

Thus, the evidence seems to be altogether overwhelming that in the great majority of cases of so-called "Acute Myelitis," and also of "Acute Poliomyelitis," the affection is caused not by an inflammation, but by thrombosis of some of the vessels of the spinal cord (where, in the latter disease, it is not due to a special acute degenerative process). Certainly, in the former affection, we have in the great majority of cases to do with Thrombotic Softening rather than with a true Myelitis.

As we have seen, this latter conclusion is rendered obvious (1) by the similarity of the morbid changes in question to those occurring in the brain which are due to thrombosis, as well as to the absence of any reason why a primary inflammation should be rare in the brain and common in the spinal cord. These strictly logical reasons are strongly reinforced by (2) the fact of the existence of special conditions favouring the occurrence of thrombosis in the vessels of the spinal cord, and in just such parts of the cord as are most frequently affected; (3) by the fact that the disease is most commonly met with in just such persons and under just such conditions (as to heart's action, blood-vessels, and quality of blood) as are known to be favourable to the occurrence of thrombosis; (4) by the fact that the mode of onset and the early symptomatology of the affection are wholly different from what they would be, had an inflammation of the cord actually existed; and finally (5) by the fact of the absence of any reasonable cause of inflammation, certainly in the majority of those in whom the malady makes its appearance.

The present confusion in regard to Acute Myelitis is, therefore, to be regarded as a reproach to scientific medicine, and one which ought to be brought to an end, especially as it is often a matter of importance, even from a therapeutic point of view, as Singer and Risien Russell have pointed out.

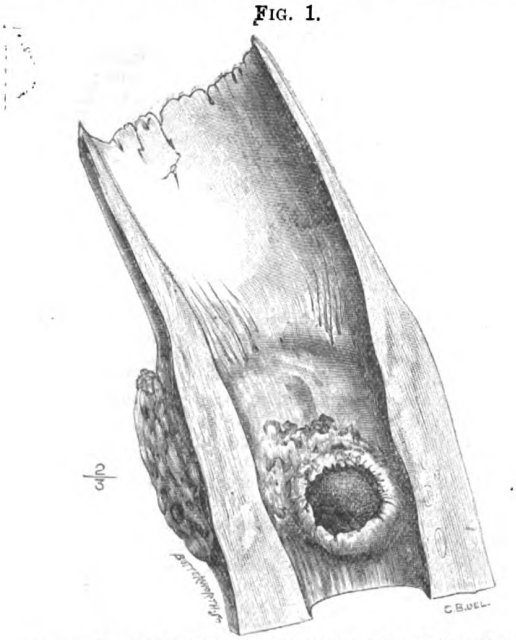
It should be freely admitted that the great majority of cases of so-called Acute Myelitis are in reality cases of Thrombotic Softening; and that in a smaller number of the cases where the disease starts as a secondary affection (cases of "Compression Myelitis" and others) there is in reality a similar absence of inflammation, and the existence merely of a degenerative and ischæmic softening of the spinal cord. As for "Chronic Myelitis," this is a term which, in the light of present knowledge, should be altogether discarded.

THE DISEASES OF ELEPHANTS' TUSKS IN RELATION TO BILLIARD BALLS.[1]

BY JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL, ETC.

THE tusks of an elephant are the permanent upper incisors. They not only surpass other teeth as belonging to an animal so enormous, but they are the largest of all teeth in proportion to the size of the body. The tusks of the elephant grow throughout life, for they possess persistent pulps, like the incisors of rats and rabbits; the only check to their growth is the wear and tear to which they are subject in digging up roots, uprooting small trees, or stripping them of bark. The tusks are also used for offence and defence; vicious bulls sometimes break their tusks fighting rivals.

FIG. 1.



Iron ball projecting into the pulp chamber of an elephant's tusk. (Museum of the Royal College of Surgeons of England.)

In Equatorial Africa the elephant attains its greatest size. A. H. Neumann gives the average height of the full-grown bull-elephant at 10½ feet. The tusks of a full-grown bull may weigh anything from 50 to 100 pounds, or more. There is a tusk of *Elephas africanus* in the Natural History Museum which is 10 feet long, 2 feet in girth, and weighs 228 pounds.

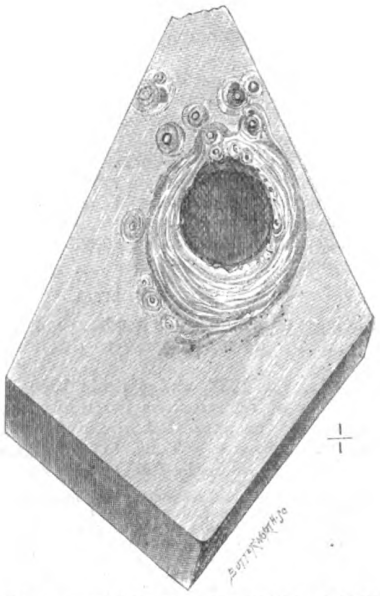
A tusk consists of two parts: a basal portion lodged in the upper jaw, and a portion which projects beyond the animal's lips. When an elephant is killed it is wiser not to attempt to chop out the tusks at once as this injures the ivory; in a few days the tusks loosen and are easily removed.

When a dried tusk is split longitudinally its basal third will be found to consist of a conical chamber, the walls of which, near its wide extremity, are very thin. The remaining two-thirds are solid, but a close examination will reveal a very narrow central area filled with irregular hard tissue representing the remains of a central canal. In the living animal the large basal cavity is filled with living tissue known as the pulp: it contains, among other things, blood-vessels and nerves. The walls of the pulp chamber are lined with a layer of cells (odontoblasts) which are concerned in forming the dentine (or ivory). The odontoblasts send minute processes known as dentine fibrils into the growing ivory: in the dead tusk the minute (microscopic) canals occupied by these fibrils persist and are termed by anatomists dentinal tubules. These dentinal fibrils are 1/1500 of an inch in diameter and so close together that they are only separated by a space slightly wider than their own diameter. Under normal conditions the active formation of dentine continues as long as the elephant lives, so that whilst the tusk is being worn down at the tip by use it is continually renewed by the odontoblastic cells in the pulp chamber.

It occasionally happens that the pulp becomes disturbed by inflammation which may be caused by injury, such as fracture of the tusks by fighting, by musket balls, by spears, or some such contrivance invented by the natives for the destruction of the elephant. Interference in a violent form with the pulp has a detrimental effect on the formation of ivory which is of some interest. That portion of the tusk which contains the pulp chamber is embedded in the upper jaw in such a manner that the open end is directed upwards.

Sportsmen who hunt the African elephant endeavour to kill this animal with what is known as a heart shot. This may be effected by shooting it through the shoulder or by a shot directed into the chest from the front. In some circumstances the hunter must take his chance of what is known as the forehead shot, and occasionally the bullet penetrates

FIG. 2.



Iron bullet surrounded by secondary dentine, embedded in the solid portion of an elephant's tusk. (Museum of the Royal College of Surgeons of England.)

to the brain. When the aim is inaccurate and the ball enters to one side of the centre of the head, it is very liable to embed itself in the large pulp cavity of the tusk, and the elephant escapes death. In such an event the pulp continues to form ivory (dentine). In consequence of the irritation caused by the presence of the foreign body, the hard material which forms around the bullet differs from true ivory, and is known as secondary dentine.

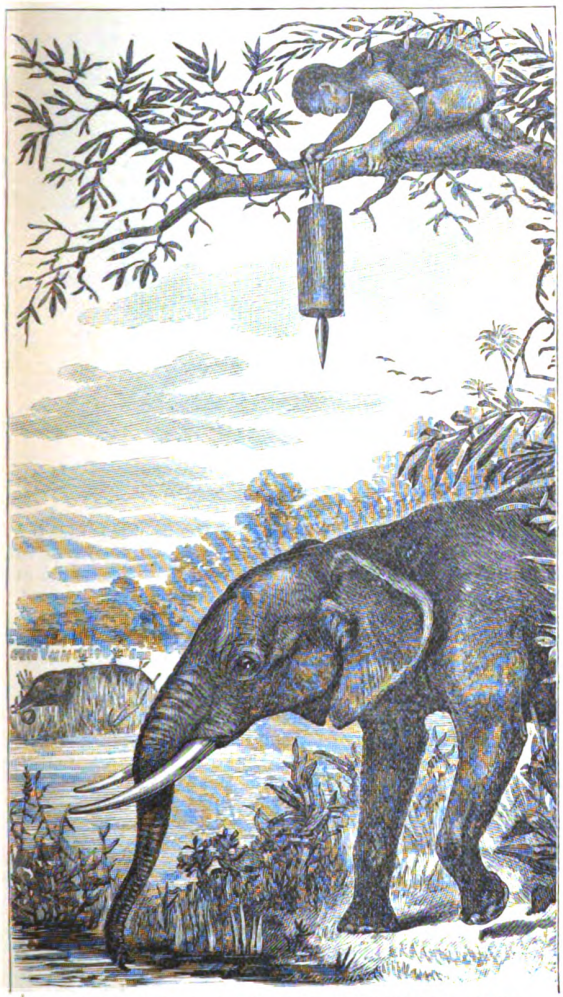
Ivory-turners have known for more than a century that hard bodies, such as bullets and spear-heads, are occasionally found embedded in the solid parts of elephants' tusks without any sign existing on the surface of the tusk to indicate the point of entry. Many observers, among them Blumenbach and Cuvier, noticed that the tissue in which these foreign bodies are embedded differs in appearance and

[1] A paper read before the Hunterian Society on Oct. 26th, 1910.

texture from true ivory. Goodsir (1841) investigated the matter and furnished a satisfactory explanation. When the ball hits the free portion of the tusk, if it only penetrates to a certain depth, no change takes place and the breach is not repaired. When the ball enters the pulp chamber through the side of the tusk the hole in the tusk is repaired by the formation of secondary dentine and the offending body is encapsuled by the same material. As the tusk advances in its socket, the bullet is gradually incorporated in the solid ivory. The thorough way in which a bullet may be embedded in the solid part of an elephant's tusk, and no mark betray it, is proved by the fact that one has been found in a billiard ball. Such a specimen is preserved in the Museum of the Royal College of Surgeons, England.

These things happened in the days of muskets and black powder: the introduction of the rifle and high velocity bullets has completely changed elephant shooting. African elephants are often killed by a single well-placed bullet. Compare this with the description of the shooting of the famous elephant, Chunee, in 1826 at Exeter Change, a wild

FIG. 3.

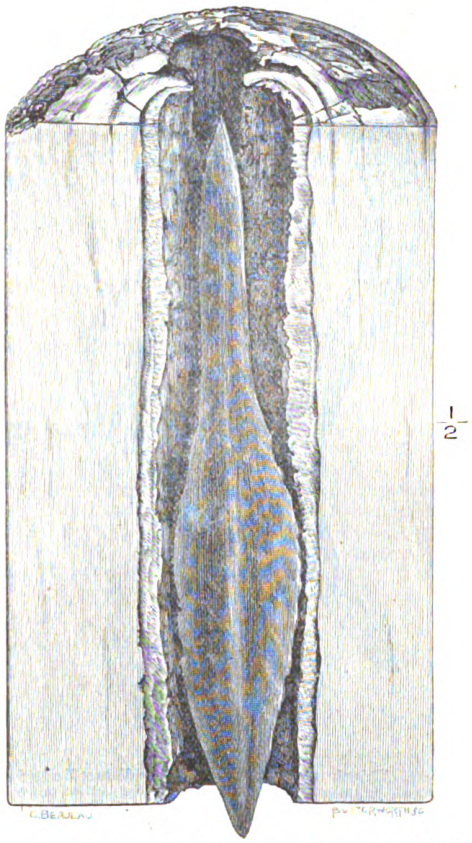


A sketch illustrating one method by which the African native attempts to kill an elephant. He drops a heavily loaded spear upon the animal when visiting a drinking pool.

beast show off the Strand near the Lyceum. Chunee became dangerous and a detachment of infantry was employed to kill him: 100 bullets were fired into the wretched animal for this purpose. The skeleton of this elephant is preserved in the Museum of the Royal College of Surgeons of England. When the skull was examined after the skeleton had been macerated a large abscess was found at the root of one of the teeth, which partly accounted for the trouble Chunee caused his keepers. When we reflect on the agony human beings suffer in consequence of an abscess in the pulp of a molar tooth, it appears difficult to estimate the suffering endured by an elephant when the pulp of a tusk is inflamed.

It is possible for a solid body to enter the pulp chamber without penetrating the wall of the tusk. The open end of the tusk looks upwards, and as the natives have a way, among others, of killing elephants by dropping a heavily loaded spear upon them from a tree, or as the result of a trap, it sometimes happens that the spear penetrates the open end of the tusk and is lodged in the pulp. The frightened animal rushes about, breaks the shaft of the spear, and leaves the iron head embedded in the pulp chamber. Such a weapon becomes embedded in secondary dentine, as in the case of a bullet, and is eventually found in a hard part of the tusk.

FIG. 4.



Portion of an elephant's tusk in section. An iron spear 7½ by 1½ inches is enclosed in a capsule of secondary dentine. There was nothing on the exterior of the tusk to indicate its presence. (Museum of the Royal College of Surgeons of England.)

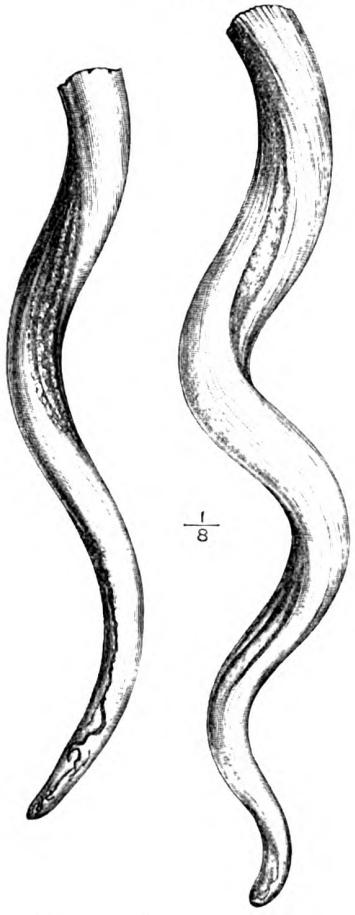
These elephant spears are formidable things. Stanley refers to one found in his second journey from Fort Bodo to the Albert Nyanza, shortly after leaving the Ituri River, in the following terms: "On the road before leaving the bush we passed a place where an elephant-spear had fallen to the ground, and buried itself so deep that three men were unable to heave it up. Such a force, we argued, would have slain an elephant on the instant. (April 8th, 1888.)"

It is quite common to find evidence of disease in elephants' tusks. Large masses of secondary dentine as big as potatoes are often found in tusks, occasionally free in the pulp cavity, more often attached to its inner wall. Sometimes a tusk consists of a wall of variable thickness enclosing a cavity extending throughout its length, into which the hand and forearm can be easily introduced. The cavity of such a tusk usually possesses rough masses of secondary dentine on its walls. It is not uncommon on dividing the solid part of

a tusk to find a piece of secondary dentine completely embedded in the ivory. Small pieces of hard tissue resembling in size and shape split peas or beans are very common in tusks. These defects are known in the trade as "beans."

Every large collection of tusks contains some of a spiral shape. The abnormal curving is due to disease limited to a part of the pulp causing the ivory to be formed more slowly on one side than the other. Some of these spiral tusks contain large tracts of secondary dentine.

FIG. 5.



Spiral tusks. This abnormal curving is due to disease limited to a part of the pulp causing the ivory to be formed more slowly (and badly) on one side than the other. (Museum of the Royal College of Surgeons of England.)

Among the many interesting objects made from elephants' tusks are billiard balls. A good ball should be perfectly spherical, but it continually tends to become ovoid. Tusks recently removed from elephants are described as "green." As ivory dries it whitens, tends to become brittle and break up into concentric layers. When a tusk is divided transversely the cut surface has an elliptical outline. In the middle of the section there is a rounded piece of secondary dentine representing the remains of the pulp chamber. Ivory-turners call this the "nerve." The ivory is deposited in layers, therefore the cut surface offers a series of concentric rings; these are more obvious in green tusks. The outer layer is technically known as "bark." As ivory dries it shrinks, and experience has taught the ivory-turner that a tusk shrinks more in width than in length. To meet this peculiarity the best billiard balls are prepared from tusks which have a diameter very little greater than that of the ball. Under such circumstances the shrinking will be fairly uniform. The tusks of cow-elephants are preferred for making billiard balls, especially those which weigh about 12 to 16 pounds. They are not so curved as larger tusks, and the so-called nerve is less conspicuous. In selecting tusks for making billiard balls it is necessary to take those in which the nerve is central, otherwise the ball will have a bias and be unreliable.

The remains of the pulp chamber can always be detected in a billiard ball; the better the ball the smaller the area of the secondary dentine. In the spot ball the bead is usually let into the "nerve." On one occasion a billiard ball received a smart stroke from a cue; to the astonishment of the player a large core of secondary dentine as thick as a thumb fell out. This core traversed the complete axis of the ball. The specimen is preserved in the Museum of the Royal College of Surgeons.

The billiard ball is turned in the rough and kept in a warm room at an equable temperature for two years; it is then turned true. A well-seasoned billiard ball should be a perfect sphere with a diameter of $2\frac{1}{16}$ inches, and weigh 5 ounces. The contour of an ivory ball is always changing; it tends to become ovoid. In addition to this inherent change, a billiard ball contracts with cold and expands with heat. During a match expert players take care to avoid the balls becoming chilled by currents of cold air, as they are then irresponsive to fine strokes.

FIG. 6.

Transverse section through an elephant's tusk, showing its elliptical outline, remains of the pulp chamber, the concentric rings, and bark.

There is something very characteristic in the "click" when two balls cannon: some players believe it to be inimitable. Some years ago two men in New York were at billiards, and the player claimed a cannon; the opponent disputed it. A friend in the room supported the player's claim, he "heard the click." Later on, when playing had been discontinued, they heard the "click of contact," but it was produced by a mocking bird in the saloon.

All billiard balls look alike to an untrained eye; they seem alike to inexperienced players but not to experts. An untrue ball will run comparatively straight under a smart stroke from the cue. A stealthy stroke from an expert player reveals flaws in the contour of the ball or of the cloth. Imagine, then, the suffering which Sir William Gilbert inflicts on the billiard sharp in his delightful comic opera, *The Mikado*, when he condemns him to play extravagant matches—

> In fitless finger-stalls,
> On a cloth untrue,
> With a twisted cue,
> And elliptical billiard balls.

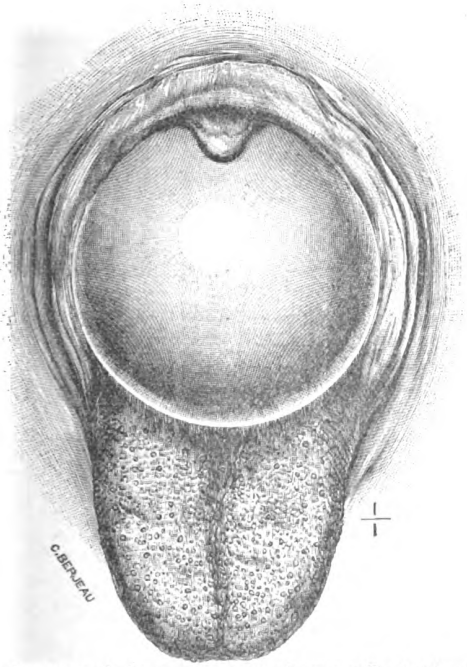
Some years ago a billiard-marker living near the Middlesex Hospital used to amuse the players by placing a billiard ball in his mouth. On one occasion the ball slipped back into the pharynx and he could not get it out and became asphyxiated; in this plight he was conveyed to the hospital and died on the way.

In mediæval times the amount of ivory exported from Africa excited the astonishment of travellers. To-day the best and largest tusks come from Equatorial Africa, and the number exported excites the curiosity of tourists. The industrial world requires and obtains 500 to 600 tons of ivory annually. Ivory sales are held in London four times yearly. At the quarterly ivory sale held in July, 1910, the tusks

offered for sale weighed 66¼ tons; they were imported from East Africa, West Africa, Abyssinia, Soudan, and Siam. In addition to elephants' tusks there were tusks from the following animals: walrus, narwhal, hippopotamus, wart-hogs, and boars; also a quarter of a ton of rhinoceros horns.

In Great Britain the best ivory is used for making billiard balls. The largest tusks are bought for the American market. 50 per cent. of ivory imported into America is used for piano keys. In India large quantities are imported for making bangles. The best tusks fetch in the open market from £68 to £70 per hundredweight. In British East Africa an elephant tusk weighing over 80 pounds is as good as a bank-note. A visit to an ivory sale teaches that even chips are too valuable to waste. They are offered for sale by the ton. When ivory chips are calcined in a close vessel they furnish

FIG. 7.



The tongue and pharynx of a man who was suffocated by a billiard ball. (Museum, Middlesex Hospital.)

charcoal. This, known as ivory black, forms a pigment for oil and water-colours; also an ink for printing engravings.

Some notion of the life of an ivory trader, with which slave trading was also combined, may be gathered from a perusal of Bode's "Life of Tippoo Tib." When this enterprising Arab raided Nsama's country, among other booty he secured 1950 frasilas of ivory. Tusks at that time were worth £7 per frasila (35 pounds). In some of the villages deep in the interior of Africa a pair of large tusks could be bought for a few yards of cotton sheeting or some beads.

Mr. F. J. Jackson traversed the slopes of Elgon in 1891. He found elephants' tusks cheap and plentiful; the natives had no use for them except to make armlets, &c. A 16-pound tusk could be purchased for six strings of beads. The difficulty was not so much in obtaining ivory, for the traders were well armed, but in conveying it to the coast, especially as it had to be carried by men; often one tusk makes a load for a porter.

The hunt for ivory in Africa has had some of the romance and been attended with as much misery as the search for gold entailed on the natives of South America. In days gone by every elephant tusk brought to the coast by Arab caravans might be regarded as a silent record of human misery and woe.

THE annual festival dinner of the West Ham and East London Hospital will take place on Friday, Dec. 2nd, at 7.30 P.M., when the chair will be taken by the Right Hon. Ailwyn E. Fellowes, vice-chairman of the Great Eastern Railway.

DIFFUSE LIPOMA.

BY SIR JONATHAN HUTCHINSON, F.R.C.S. ENG., F.R.S., &C.,

CONSULTING SURGEON TO THE LONDON HOSPITAL.

IN THE LANCET of Sept. 10th last (p. 848) a letter of mine was inserted asking as to the condition known as diffuse lipoma of the nape, whether it had been observed in the lower animals. Two months' silence may perhaps be taken as a tacit negative. My object in putting the question was to ascertain whether others could confirm an observation of my own that these lumps are sometimes seen in asses. Since my letter some new and strongly confirmatory observations have accrued which I now venture to record. I have been told these "lumpy necks" are not very uncommon in asses, and sometimes cause curious mistakes. They are occasionally so large that they displace the mane (usually in the ass erect) to one or other side and make it in part one-sided. I have heard of a case in which a tender-minded observer mistook the mass for an abscess, and made complaint of cruelty to the animal. He was assured, however, by a veterinary surgeon that the soft mass was nothing but fat, that the condition involved no pain whatever, and that it was not very uncommon. My own attention to the subject was first attracted by accidentally finding these lumps in the neck of a fine gelding ass belonging to a neighbour of mine at Haslemere. The animal is very sociable and came up to me in the field, hoping to be fed, and was very willing to be stroked. A companion drew my attention to the great width of its neck under its mane. The masses rest like two thick polony sausages, bulging one on each side of the root of the mane.

I must preface a few words as to the true nature of these growths. An important inference from paleogenetic speculations is, as I have elsewhere pointed out, that in all allied animals parallel conditions may usually be recognised. Thus a patch in the middle of the lower back which in the porcupine is so organised as to grow quills will in other animals produce, it may be, coarse hair or, it may be, hair which only differs from the rest in its colour. The "dorsal streak" running the whole length of the back is common to all animals and receives at different parts in its length peculiar modifications. In the lower part it may grow the porcupine's quills and in the upper part it may produce, what is far more common, a *mane*. The mane consists of one or more rows of deeply implanted strong and coarse hairs. The roots of these hairs lie embedded in coarse granular fat which adheres in continuity with the true skin above it. The result is that a thick mass is formed at the base of the mane which is firmly continuous with the overlying skin, but is more or less loosely attached to the structures beneath it. As might be expected, this mass (hair-roots, glands, fat, and fibro-cellular tissue) is liable to its own more or less peculiar forms of disease. In many animals there is no conspicuous excess of hair, and in many there is likewise no excess of fat, but in the necks of almost all animals the skin is thicker and firmer in this part of the neck than elsewhere. In the human subject the mane is suppressed, but not absolutely so.

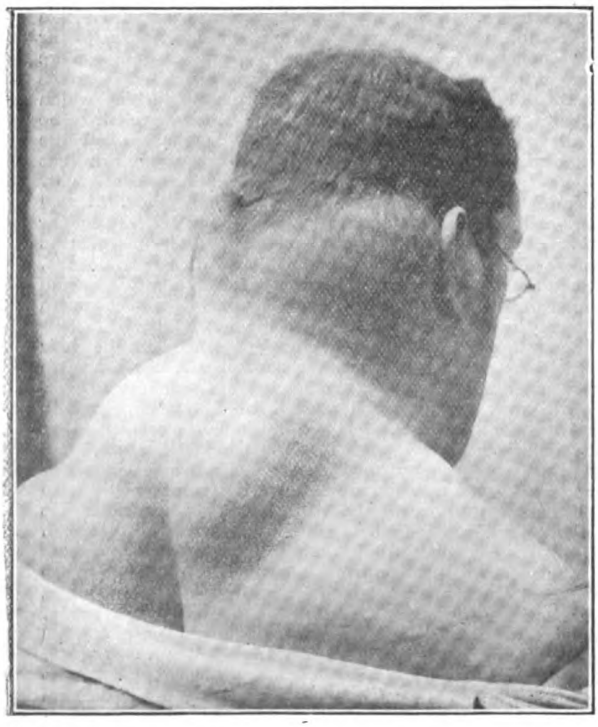
Sometimes disease may be located chiefly in the hair follicles or glands, sometimes the structures of the true skin may undergo hypertrophy, and in others a tendency to overgrowth may appear to be almost exclusively expended in over-development of fat. It is from the latter condition that the enlargements with which we are now dealing originate. They are paleogenetic aberrations in the human subject of the base of the mane in animals. Until recently they have been supposed to occur only in the human subject, but recent observations have led me to think that, as might have been expected, they occur also in some of the domestic animals.

Nor must we, although we attach great importance to the region of the mane as giving to these growths their special location, narrow our observations to that region only. Wherever there are deeply placed hair follicles embedded as they always are in fat, there such hypertrophies may occur. These conditions occur very definitely in the region of the pubes. The pubes is, I believe, in a very unusual position and in the case to which reference is made below the condition existed in unusual excess, for although I have often seen slight examples I have never before seen any condition approaching it, nor do I find any record of such cases.

FIG. 1.

Fat tumours symmetrically placed on the back of the head and neck—quadrate or "nates and testes." (Copied from McCormac's paper.)

FIG. 2

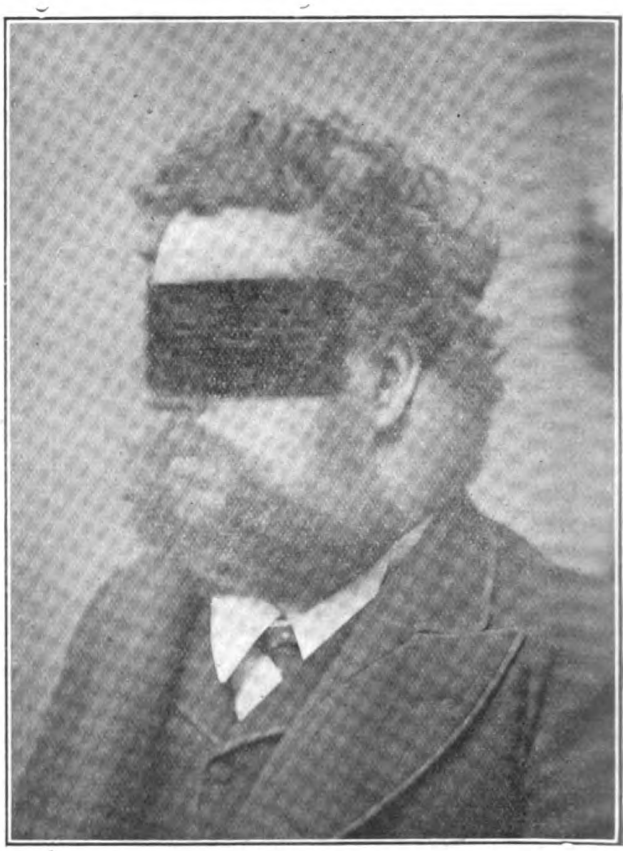


Fat masses symmetrically arranged on the back of the head and lower neck-quadrate or "nates and testes." (From the same patient as Fig. 3.)

FIG. 3.

Fat tumours in the front and sides of the neck. (From the same patient as Fig. 2.)

FIG. 4.



Fat tumours symmetrically placed on the back of the neck and extending forwards on the jaw. (Copied from my own paper in *Archives of Surgery*.)

The occurrence of these fat tumours on the nape of the neck in the human subject has been observed by many and has been especially written about in England by Mr. Morrant Baker, Sir William McCormac, and others. One of the illustrations here given (Fig. 1) is copied from one of McCormac's illustrations. The patient whose fat tumours are shown in Fig. 2 and Fig. 3 had also fat tumours symmetrically placed on the pubes and concealing the penis.

I have as yet personally examined only two definite examples of the "diffuse lipoma of the nape" in the donkey. Several others have been mentioned to me. So far as my inquiries have gone it appears to occur in castrated males of middle age which have been well fed. Although I have been told that they are very fond of beer, no one has suggested that they are likely to get much of it or to be fed with "grains." All the cases are alike but with great differences as to degree, slight forms being, in asses as well as in men, very common and extreme instances rare. I have not as yet in asses observed the condition in other parts than the root of the mane. A certain amount of thickening of the mons is common in both sexes, but the example which I have mentioned is the first and only one which it has been thought worthy of publication.

Haslemere.

THE PROGRESS OF INFECTION IN PHTHISIS.

CONTAINING A PLEA FOR THE TREATMENT OF EARLY CASES BY ABSOLUTE REST.

BY L. COBBETT, M.D. CAMB., F.R.C.S. ENG.,
LECTURER ON PATHOLOGY, UNIVERSITY OF CAMBRIDGE.

BEING a pathologist and no physician, I feel that I ought perhaps to apologise for venturing to write anything concerning the treatment of disease. Yet, while I clearly recognise that clinical experience only can establish the value of any treatment, I see also that the latter must be good or bad precisely as it corresponds, or fails to correspond, with the processes going on in the body. I therefore hold that it is legitimate for pathology to point to principles upon which methods of treatment may tentatively be based. I know, of course, that many a useful method has arisen from erroneous conceptions of disease, and that others, useless and even harmful, have been based upon crude views of pathology. Yet I think it cannot be doubted that if one knew accurately and in detail the true pathology of any disease, there would be no difficulty in deciding how to treat it.

My opportunities of studying tuberculosis hitherto have been mainly in the laboratory and post-mortem room and very little at the bedside. They have been derived largely from experiments upon the lower animals, many of them made in the laboratories of the Royal Commission on Tuberculosis at Stansted. But whatever the primary object of any given experiment, I have always tried by every means to gain some light on the nature of susceptibility and resistance to infection, and of the other conditions which help to determine the severity of an infection and the course it runs. Such observations, as well as others made in the course of experiments planned more particularly with the object now under consideration, have led me by degrees to form conceptions as to the way the body attempts to defend itself against invasion by the tubercle bacillus, and how it is that the bacillus so often succeeds in maintaining its hold. It is only recently, however, that the occurrence of pulmonary tuberculosis in more than one of my friends has strongly turned my thoughts towards questions of treatment, and has led me to inquire what is the pathological sanction for the methods actually in use, and which of the details of treatment are of the greatest importance. I do not claim any originality for my views, merely that they are the result of my own observations. I cannot hope to deal at all fully here with the question of the bearing of pathology on the treatment of phthisis, but merely to put forward some points which my experiences have impressed upon me.

Immunity the Cause of Recovery.

Let me put my argument in my own way and begin at the beginning. I remembered, in my early student days, being puzzled to explain the possibility of recovery from a microbic disease. How was it, I asked myself, that the patient finally triumphed over the vast host of invaders which had grown out of the few which first caused the infection, after he clearly had been unable to resist the attack of those few at the outset? The problems of immunity were then, as now, attracting much attention; and I well recollect with what a flash of illumination appeared the idea that the immunity conferred by one of the specific fevers must be due to the acquisition of new, or at least improved, powers of resisting the specific germ which causes them, and that *the very perfecting of the powers of resistance, which is the cause of the immunity which follows an attack, occurs during the course of the disease, and is actually the cause of recovery.*

Now the immunity which follows an attack of one of these diseases is specific—that is to say, the body has acquired new powers of resistance to one particular species of microbe and to no other, and since the cause of immunity and recovery are the same it follows that the cause of the latter is specific also. That it has little in common with what one calls the general state of the patient's health is shown by the fact that when they are most effective, as, for example, at the crisis of pneumonia, the patient's general health is manifestly far inferior to what it was at the moment of infection.

My first point, then, is that *the cause of recovery from infectious disease is the acquisition of specific immunity.*

Does Tuberculosis Confer Immunity?

With many infectious diseases it is a case of kill or cure, as, for example, with small-pox, in which either death follows quickly on infection, or immunity is established and the patient recovers. Tuberculosis is not of this kind. It is a comparatively slow disease, runs no definite course, and has but a feeble tendency to recovery. On the contrary, it too often continues to progress, more or less irregularly, and even if it becomes arrested one can never be sure that it will not recur. This disease then, as we see it at the bedside, does not appear to confer immunity, and this would seem to be the cause of the absence of any definite tendency to cure.

This view of tuberculosis is probably not wholly justified, and I think I shall be able to show that tuberculosis differs from other diseases, in the points which we are now discussing, only in degree, that this disease does indeed confer some immunity, though of a feeble kind, and that in this, as in other and more acute infections, the hope of recovery must be based on the acquisition of this immunity. That recovery is frequent, at least from the early stages of infection, is well recognised at the present day, and is proved by the great frequency with which healed, or at least quiescent, tuberculous lesions are found after death from other causes, lesions which, in the majority of such cases, have never been detected during life.

The Evidence of Immunity in Tuberculosis.

Many experimenters have attempted to produce immunity to tuberculosis in animals, and not altogether without success. Experiments made for the Tuberculosis Commission have convinced me that some degree of immunity to bovine tuberculosis can be induced in calves by injecting them with cultures of tubercle bacilli of the human type. Others have succeeded by different methods. But whatever method is used, even if the injections be repeated, the immunity attained is variable, and is never of high degree. It is not to be compared for a moment with that which may be induced in the horse against diphtheria. But while one clearly recognises this difference in degree, one cannot ignore that some kind of immunity to tuberculosis can be experimentally induced in animals.

In tuberculous man, too, there is evidence that some immunity to tuberculosis occurs. I am not now referring to those cases which recover without ever having been diagnosed, though such might be cited to the point, but rather to the more chronic cases of phthisis. For consider, the patient's lungs in such cases must often contain enormous numbers of tubercle bacilli, since they are constantly escaping in the expectoration and in such numbers as to set up an acute and rapidly fatal tuberculosis in susceptible individuals who happen to come within range of infection, and who receive a dose which is doubtless only a small fraction of the bacilli in the body of the original host. If one were to take, let us say, one-tenth of the bacilli in the body of such a patient and inject them into a healthy individual, no one, I think, could doubt—at least, no one who has had any

experience of experimental tuberculosis—that the recipient would rapidly die from acute miliary tuberculosis, and yet the original patient with ten times the number lives on.

Again, whether one accepts the statements of those who claim to find tubercle bacilli in the peripheral blood-stream of phthisical patients or no, one cannot doubt that stray bacilli occasionally find their way there. And yet persons with well-established phthisis hardly ever die from general tuberculosis. When generalisation does occur in tuberculosis it is almost always early in the course of the recognised illness. In such cases a lesion, indeed, may possibly have existed for a long time, but it has caused little or no disturbance, probably not enough to call forth any improvement in the powers of resistance.

The rarity of generalisation in cases of phthisis, then, together with the chronic course it runs in many cases in spite of the enormous numbers of bacilli present, lead me to regard the disease in such cases as running its course in a partially immunised individual, and I conclude that *tuberculosis in man does tend to confer some immunity, and that it is on the acquisition of the new or improved powers of resistance which are the cause of this immunity, slight though they be, that the hope of recovery mainly depends.*

What, then, are the new or improved powers of resistance to tuberculosis upon which so much depends? It is impossible as yet to give a satisfactory account of them, and it would take too long to discuss the question at all fully. But some kind of a rough answer may be gained by considering the lesions produced, for the lesion represents the structural reaction made by the body, *plus* the destructive effects of the bacilli and their poisons. Let us then consider lesions which progress up to a point and then recover—namely, those produced by subcutaneous injection into the calf of tubercle bacilli of the human type; for these, if used in large quantities, cause a very considerable tumour to appear at the seat of injection, and the infection undoubtedly takes root and makes some progress for a time, and yet recovery always takes place, no matter how large a dose has been given or how susceptible the calf. The tumour at the seat of inoculation is doubtless at the onset caused by the endotoxin contained in the large mass of bacilli introduced, and which slowly escapes from them, probably as the individual microbes perish. This toxin has a twofold action, causing necrosis where it is most concentrated—namely, immediately around the bacilli—but acting merely as a stimulus to cell division at a greater distance, at least upon the hardier elements of the tissue, such as the endothelial cells. In the mass of necrotic tissue around them the bacilli find protection from the bactericidal agents which the body would otherwise be able to bring against them, and they flourish and multiply exceedingly. The animal tissues in the meantime, unable to destroy the bacilli, build around them a wall endowed with high powers of resistance, composed mainly of fibroblasts and lymphocytes, much as in the analogous case of pyogenic infection an abscess wall arises around the pyococci and the pus which affords them shelter.

But the infection thus checked is not immediately brought to an end. In this form of tuberculosis, as in suppuration, the necrotic mass continues to enlarge at the expense of the surrounding granuloma tissue, which is probably continually perishing on the one surface and reforming on the other. Thus the necrotic mass increases, but the protecting wall retreats before it and continues to bar the way of escape to the bacilli. In the calf subcutaneously injected with 50 milligrammes of tubercle bacilli of the human type the tumour at the seat of inoculation may sometimes be of considerable size, and the neighbouring lymphatic glands may become greatly enlarged. The tumour, which is at first solid, caseates, and after several months its contents become fluid and bear a superficial resemblance to pus, but contain few recognisable cells. Frequently the skin ulcerates before the tumour has grown to any large size and the "pus" escapes, but even if ulceration does not occur the tumour after a time ceases to grow, and the infection becomes arrested. The animal's temperature, which has been raised for some weeks, returns to the normal, and bodily growth, which has been somewhat retarded, again goes on at the normal rate. At last, after many months, the animal appears quite well except for a diminished tumour at the seat of inoculation, and this is found to be formed by a dense wall of fibrous tissue lined by granulations enclosing the liquefied remains of the necrotic mass.

We need not stop to describe the lesions in the glands nearest the seat of inoculation; much the same changes take place there as in the local tumour, only ulceration does not occur; but something may be said of certain minute lesions which occur in distant organs. So inconspicuous are they that they seem to have escaped notice until they were seen at Stansted. They were found there in small numbers in about half the calves infected with the human type of tubercle bacilli, situated in the lungs and lymphatic glands, and sometimes in other organs. In a few cases they were quite numerous. They appeared, six months after infection, as spherical bodies, translucent, clearly defined, resembling seed pearls. They looked dark when situated in the light-coloured lung, but in the other organs they were lighter than the surrounding tissue. It was easy to pick them out cleanly on the point of a knife from the surrounding tissue, which was perfectly normal. They were partly calcareous, and sometimes contained tubercle bacilli. The source of these little healed tubercles was at first a puzzle to me, for I could not believe that in these cases the disease had progressed so far as to have become generalised in the accepted way, and then had become arrested. Experiment made with the object of studying their origin clearly showed that these little fibrous tubercles were due to the escape of small numbers of tubercle bacilli from the seat of inoculation during the first few days which followed an injection, and before the focus of infection had become surrounded by granuloma tissue; for when calves were killed within a few days of an injection bacilli were already present in small numbers in nearly all the glands and organs.

Such, then, is the history of the calf infected with tubercle bacilli of the "*human*" type. A local necrotic tumour arises at the seat of inoculation in size proportional to the quantity of bacilli injected. Some necrotic patches occur in the neighbouring glands, and little minute fibro-calcareous lesions may arise in small, or even large, numbers in distant organs. The disease always becomes arrested ultimately, the smaller lesions becoming fibrous and calcareous, the larger ones caseous and surrounded by a well-developed fibrous capsule.

When *bovine* tubercle bacilli are used the results depend upon the quantity injected. With comparatively small doses (millions in the place of milligrammes [1]) the history is very much the same as that described above, but with larger doses, such as 50 milligrammes, progressive miliary tuberculosis rapidly follows, and all the principal organs are found a few weeks later packed with small tubercles. The local lesion forms a striking contrast to that formed by tubercle bacilli of the human type, for instead of being well defined and surrounded by a well-marked capsule it is of the infiltrating type, penetrating widely into the subjacent muscle and into the overlying skin, and extending, sometimes obviously, along the lymphatics.

These observations on the lesions of calves injected with tubercle bacilli of the human and bovine types respectively lead me to believe that the powers of resistance which develop during infection, and which lead in favourable cases to cure, are partly local and partly general. Experiments made many years ago on the cause of the local immunity caused by erysipelas lead me to think that it is not improbable that the local powers of reaction become quickened and improved; possibly the endothelial cells become less sensitive to the poison, owing, it may be, to the development of an antibody, so that they now react by multiplication to a concentration of poison which originally would have caused necrosis. But whether the local powers of defence undergo improvement or not, we must believe that they hold the disease in check until new or improved constitutional powers, whatever they may be, have had time to become evolved, and so far perfected that the disease is arrested.

The Influence of Dose.

One lesson which strongly impressed itself on my mind when I was working at Stansted was that the severity of an experimental tuberculosis depends largely upon the number of bacilli used to provoke it. The evidence of this is fully reported in the Second Interim Report of the Royal Commission on Tuberculosis, Appendix, Vol. III., p. 257. I therefore need to quote only a few examples here. A heifer and a calf each received a subcutaneous injection of a 50-milligramme culture of bovine tubercle bacilli, while another

[1] Eastwood estimated that 10 milligrammes of bacilli contained 45,000,000,000 individuals.

heifer and another calf received a far smaller dose, calculated to contain 1,800,000 tubercle bacilli. The two first-mentioned animals developed an acute general tuberculosis which was rapidly approaching a fatal termination when they were killed 54 and 34 days respectively after injection, while the other two which received small doses remained well, and when killed 413 and 202 days later respectively were found to have only small calcareous nodules at the seat of injection and a few minute calcareous foci elsewhere.

Several other equally striking examples might be given, but it will suffice to mention the comparative effects of 50 milligrammes and 10 milligrammes of culture respectively injected subcutaneously into calves. There was reason to think that the virulence of the different strains of tubercle bacilli of the bovine type used in these experiments did not differ appreciably from each other; at least, our methods were not delicate enough to show any difference. Forty calves[2] were subcutaneously injected with the larger dose. All but one died from general tuberculosis in less than three months, the average length of survival being 33·7 days. Forty-one received the smaller dose, and of these 11 (27·5 per cent.) were alive and in fairly good condition at the end of three months; while those which succumbed did so after an average survival considerably greater than that of those which received 50 milligrammes—namely, 44·5 days.

These results were obtained with viruses of the bovine type which had been grown in artificial culture from cases of tuberculosis in children. A. S. Griffith obtained identical results when working with cultures derived from the cow.[3] Of 34 calves which were injected by him with 50 milligrammes of bacilli one only survived three months; the others either died or were in a dying condition when killed 30–40 days after injection. Twelve calves were injected with 10 milligrammes. Of these, four survived three months (33 per cent.).

The Influence of Individual Differences of Susceptibility.

It was usual at Stansted to inject two, and sometimes more, calves simultaneously with the same material in order to avoid errors which might arise from differences of susceptibility of the individual animals. These experiments therefore are well suited to show to what extent differences of individual susceptibility affected the result of such inoculations. Moreover, if we are satisfied that all the viruses used in a given series did not differ in virulence from one another, then one can compare together the individual susceptibility of all the calves which received the same dose of these viruses. In both Griffith's series and my own when 50 milligrammes of bacilli were used differences of individual susceptibility among the calves used exerted but little influence on the result. It is true that in each series out of 30 or 40 calves one was found strong enough to survive three months after injection. Yet all the rest died, or were dying when killed, in about five weeks. When 10 milligrammes were injected differences of individual susceptibility were much more evident. From 27·5 to 33 per cent. of the calves in each series survived three months, and some of these had very little the matter with them, while their fellows which had received the same injections died in from three to nine weeks. Frequently it was seen in a given pair which had received the same injection, and which were identical in age, size, and appearance, that one would die rapidly from general tuberculosis and the other would hold out well for three months.

These results prove beyond question that when the calf is experimentally infected with tuberculosis by subcutaneous injection the dominating factor in determining the severity of the resulting disease is the dose of tubercle bacilli injected, and that differences of individual susceptibility in the animals exert a determining influence on the result only when the dose of infecting bacilli lies between certain limits. In other words, no calf has resistance enough to overcome a really large dose, nor did our experiments show any calf feeble enough to succumb to a very small dose.

Now, are we justified in applying these conclusions, based, as they are, on experimental tuberculosis in one of the lower animals, to the disease as it occurs naturally in man? First, let us take the method of experimental infection—namely, subcutaneous injection with quantities of bacilli far larger than any which by any natural means could possibly enter the body. Subcutaneous infection is clearly not a close imitation of any natural means of infection, yet in one respect it is not so very unlike. I have already stated that during the first few days which follow a subcutaneous injection many bacilli wander from the seat of inoculation and reaching the blood get carried all over the body. This, except for the numbers of bacilli which reach the blood, is very much what must happen when tubercle bacilli, having entered through the lungs or intestines—it matters not for the moment—settle in some internal part, as, for example, the hip, and set up tuberculosis there.

The numbers of bacilli used in the experiments were far larger than any which by any possibility could get into the body under natural conditions. I have already mentioned that in order to produce a certainly fatal infection in the calf one had to inject 50 milligrammes of young culture. Still larger quantities had to be used to infect by feeding. The necessity for using these larger quantities was not because the bacilli of artificial cultures are attenuated, for even when emulsified lesions were used instead very large numbers of bacilli, as shown by the numbers counted in a small sample, had to be employed. Such quantities as one had to use to get a progressive infection would, then, appear to be of an altogether different scale of magnitude from any which gain entrance to the animal body under natural conditions One is tempted to agree with the opinion that infection does not occur under natural conditions unless some circumstances have for a time lowered the bodily resistance. But even if this be true it affords no reason for thinking that variations in the size of the dose do not produce corresponding differences in the severity of the resulting disease in cases of natural infection, just as they do when the far larger doses are given in experimental tuberculosis. Only in the former case, where abnormally susceptible individuals alone get infected, the variations in the dose which produce the differences in the severity of the disease lie between entirely different limits of size than they do in the latter case, where animals of normal resistance are employed.

Secondly, may we apply conclusions based on tuberculosis in the calf to that occurring in man? I think we may, for both man and the ox react very similarly to tuberculosis—the one, that is to say, to tuberculosis caused by the human type of tubercle bacillus, the other to that caused by the bovine. Both species possess very considerable powers of resistance. That man resists well we know, because so many infections, after having made some slight progress, become cured, and are only discovered in the post-mortem room. The ox resists we know, because small doses of bovine tubercle bacilli are insufficient to infect him, and even 10 milligrammes are by no means certainly fatal. In both species, too, natural tuberculosis often runs a chronic course. It is true, no doubt, that acute general tuberculosis is commoner in man than the ox. The latter, then, has probably in general a higher degree of resistance than man, yet I think that on the whole the two species are fairly comparable in this respect, and I believe that we shall not greatly err if we conclude that *in man as in the ox the severity of a tuberculous infection is largely determined by the number of bacilli which gain entrance at the start.*

This conclusion is further supported by the following consideration. I have already argued that in well-established cases of tuberculosis in man the disease is running its course in a partially immunised host. In such cases bacilli must from time to time escape into the blood stream and be carried to distant organs, yet no lesions occur in such organs as the liver, spleen, or meninges, which are commonly affected in general tuberculosis, yet the intestine and mesenteric glands frequently become affected. This immunity of one set of organs, together with the liability of the others to become affected, can hardly be due to any other cause than that the one receives only small quantities of bacilli from the blood, while the others are exposed to the enormous numbers which get swallowed from time to time.

At first sight it may not be easy to see why the dose of invading bacilli should play so important a part. It has been urged on the other side that since the bacilli multiply it cannot matter what the initial number of invaders may be, because a small number will soon come to be as many as a larger one.

The explanation of the influence of number of invaders on the resulting infection seems to me to depend partly on the

[2] For diagram illustrating this see loc. cit., vol. ii., p. 1029.
[3] Loc. cit., vol. i., opposite p. 4.

fact that the bactericidal substance in the blood of a normal person is strictly limited (it will suffice for a few bacilli, but not for a large number), and partly on the fact that the bacilli contain in their bodies a necrotising endotoxin, and the more there is of this at the start the more secure will the invaders be against the attack of the animal's defensive forces. But these explanations only serve to explain successful infection on the one hand, or total failure on the other; they do not explain, what is undoubtedly the case, that the size of the initial dose makes all the difference, even in the case of infections which progress at least for a time, and in which the bacilli undoubtedly increase in number. We are therefore thrown back upon the explanation that the powers of resistance, local or general, or both, augment from the very commencement of infection. So that when we put a small dose of bacilli into an animal the powers of defence immediately begin to augment, and have already become notably more efficient by the time the bacilli have come to equal in number the dose which would have proved fatal had it been injected at the outset.

I have so far endeavoured to show that in its tendency to induce immunity tuberculosis differs from most other bacterial diseases only in degree; that during the course of infection the powers of resistance are constantly increasing; moreover, that the severity of the disease depends, other things being equal, on the numbers of bacilli introduced at the onset. If these points are well established, it follows that as tuberculosis runs its course and the capacity of resistance increases *it will require as time goes on an increasing number of bacilli to infect any new region of the patient's body.*

Why is Pulmonary Tuberculosis more fatal than other forms of Tuberculosis confined to a Single Organ?

The answer to this question is, I submit, because there are in the lungs facilities for the spread of infection which do not exist elsewhere. In order to make this clear we must follow a little further the method of the spread of tuberculosis in the body. When a protective wall of granuloma tissue has been built around a focus of tuberculous infection the extension of the disease from that focus to distant parts is more or less completely prevented. The lesion, however, continues to increase in size. The necrotic mass grows at the expense of the surrounding granuloma tissue, while the latter continues to extend at the expense of the surrounding lung tissue. By degrees little neighbouring foci of infection run together, and thus the lesion grows locally until it either reaches a surface or the growth of the bacilli becomes arrested. Even the former occurrence is favourable to recovery, just as is the bursting of an abscess, for the mass of dead tissue which gives cover to the bacilli, together with many of the bacilli themselves, gets cast off. For this reason tuberculosis of the superficial lymph glands, when it does not rapidly lead to generalisation—that is to say, when the reparative process has once got thoroughly into action—almost always ends in recovery.

Tuberculosis of other organs also, the lungs excepted, terminates in recovery, I think, much more frequently than equally advanced tuberculosis of the lungs. This, I would suggest, is because the lungs, on account of their anatomical structure, offer far greater facilities for the infection of new areas than exist elsewhere. From a lesion in a bone or solid organ the bacilli can only get to neighbouring parts by the lymphatics or directly by the blood-stream. The former route is well defended, the latter is a very improbable one. In the lungs, however, the tuberculous focus discharges into a bronchus, usually a small one, and the infective material is by no means so safely got rid of this way as if it had been cast off on to the surface of the skin, but before it can escape from the body it has to travel by a long road with numerous turnings. The infective matter does not escape in a single expiration, but many are as a rule necessary to expel it. And since these expirations are apt to be forcible the corresponding inspirations are correspondingly forcible, and tend to suck the infective matter down neighbouring bronchi into new areas of the lung. Thus in this organ new foci of infection are frequently arising, lighted up too often by numbers of bacilli large enough, when removed from the highly resistant tissue which previously surrounded them, to constitute an overpowering dose in the existing state of the bodily powers of resistance.

When one watches the course of a fatal case of phthisis one cannot but be struck by the peculiar course run by the disease. The patient during the greater part of the time is slowly improving, but this general upward course is marked by sharp relapses which carry him each time to a lower level than ever he had reached before. Again he improves for a time, and again relapses, and is thus carried to a lower level still. And this process is repeated with comparatively long periods of improvement and short periods of relapse, until the end. These relapses, I believe, are commonly due to the infection of new areas during the attempted expulsion by coughing of material containing tubercle bacilli.

In a case I have recently followed the patient on one occasion in the early part of his illness coughed up a little pellet as large as a split pea, consisting almost entirely of tubercle bacilli. When I saw this mass of microbes, which must have weighed many milligrammes, I could not but think that it would have been an almost certainly fatal dose had it found its way into a new part of the lung at that early stage of disease when as yet but little immunity had been attained.

Now if it is, I believe, by the infection of new areas in the way described that phthisis commonly progresses (and I am not suggesting it is the only way, but rather the commonest and most dangerous way), I cannot help thinking that the first aim of treatment should be to prevent this recurrence of infection by every possible means, or at least to delay it as long as may be, in the hope that in the meantime the bodily powers of resistance should have been raised sufficiently to overcome it when it does occur. This can only be done by controlling coughing and enforcing rest in bed. In the early stages of the disease no excitement of any kind would appear justifiable. Talking should not be encouraged, and permitted only in a low voice, laughter prohibited, and exertion of any kind avoided, the general principle being that gasping inspiration following on breathlessness is the one thing to be avoided.

It may be objected that by following these instructions, especially by confining the patient in bed, the general health will be impaired. But does this matter so much as is sometimes thought? If pathology teaches one thing clearly it is that the powers to resist any given infection and the general state of health do not always go hand in hand. If it were otherwise, how could a patient recover from pneumonia when apparently at death's door, seeing that he had been unable to resist infection when in his ordinary general state of health? In tuberculosis, too, though I do not doubt that some infections such as influenza, and some conditions such as diabetes, impair the powers of resistance, yet by no means always does the state of the general health seem to run parallel to resisting capacity. In thinking over the various acquaintances of mine who have been attacked by, and in too many cases have succumbed to, tuberculosis, I have been struck by the fact that it has been as often the apparently strong as the apparently weak who have fallen victims. Some few of them, indeed, might have been selected as ideal specimens of humanity.

Resistance, then, to tuberculosis, like resistance to other infections, is a very specific matter, and does not necessarily go hand in hand with what one regards as the general bodily health. We commonly assume that the two go together, and do everything to encourage the general well-being. We prescribe the most nourishing food, recommend fresh air, and are not adverse, in what we deem suitable cases, to moderate exercise. So far good, but I think we should ever bear in mind in phthisis the menacing danger of the infection of new areas and do all we can to avoid it, or to postpone it until the patient has become more immune. And if we can do this in the early stages by absolute rest in bed, I do not think we should be deterred therefrom by the fear that the general bodily health will suffer.

Cambridge.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce "The Dawn of the Health Age," by Dr. Benjamin Moore, the small book being also published at Liverpool by the Liverpool Booksellers' Company, Limited. The book deals in a graphic way with the organisation of a great campaign against disease, and the effect of such a warfare upon the virility and fitness of the resulting race. The author advocates a properly organised national health service on the score of efficiency and economy. The book is written for the lay public.

THE PREPARATION "606":

THE TREATMENT OF SYPHILIS BY EHRLICH'S METHOD; INDICATIONS AND CONTRA-INDICATIONS.

Observations made in Germany.

BY DR. E. EMERY,

PHYSICIAN TO THE SPECIAL INFIRMARY OF SAINT LAZARE; LATE HEAD CLINICAL PHYSICIAN OF DERMATOLOGY AND SYPHILIS, SAINT LOUIS HOSPITAL.

(*Specially translated for* THE LANCET *by* Dr. J. G. HARE, *Bacteriological Department, King's College, London.*)

THE numerous reports which made the Ehrlich remedy known, not only to the medical world, but to the world as a whole, seemed to me, from the very beginning, to deserve seriously the attention of all physicians, especially those who made the study of syphilis and its treatment their speciality. I knew that Ehrlich had sent doses of his remedy to France and that they had been applied to a number of patients by competent and experienced men, but these researches were still in their infancy, and the field of experiments seemed to me too narrow, and in consequence my investigations were so limited that it was impossible to render an exact account of the various manifestations of syphilis and parasyphilis. In Germany, the researches undertaken on Ehrlich's remedy had been, however, pursued for several months in numerous hospitals. The patients who were treated already could be counted by the thousand, and thus the field of my own observations was widened considerably. The judgment of the various experimenting physicians, valuable as it was, found support by a number of clinical facts, which were strong enough to make it possible, there and then, to obtain from them certain principles and to lay down certain rules which do not risk immediate contradiction. In short, the multiplicity of processes as employed by each operator for the manipulation and preparation of the medicament before the injection were sufficient to supply me with valuable indications on their stability and their action, so variable in rapidity and continuance. I also have to add that Ehrlich's great renown attracted me irresistibly towards him, and it was my great desire to gain direct evidence from him of his expectations and convictions. I also wished to hear from his own lips his valuable recommendations regarding the mode of employing his remedy, its indications, and contra-indications.

None of my hopes were disappointed. Introduced to the great German doctor by a letter from Professor Alfred Fournier, who strongly advised me to undertake this journey, I can say, not without pride, that the name of my illustrious master acted like a charm upon the stranger, and that his own person and his work enjoy there the highest esteem. He assured me, even though he was already in correspondence with some of my compatriots, that I was the first French physician who had come to visit him for the purpose of inquiring into his discovery at his own laboratory.

I will not dwell here upon the conversations which I have had with the great man on various occasions, for this article is to make known the principal recommendations which he was good enough to give me; and he honoured me by entrusting me, without enforcing any restrictions regarding its employment, with a considerable quantity of his valuable preparation, which placed me in a position at once to commence the therapeutic applications which I pursued with activity.

In Professor Ehrlich's laboratory experiments are now being made upon animals. The applications of "606" to human beings are practised in clinical establishments and special hospitals of various towns under the direction and superintendence of experienced and prudent physicians who willingly allowed me to inspect their laboratories and wards. Some thanks are due to them as well for having allowed me to back up my knowledge by their own experience. I wish here to express to them my deepest gratitude. The observations which are to follow have been gathered principally from the practice and clinics of Professor Herxheimer of Frankfort, Professor Lesser of Berlin, and the physicians Wechselmann, Michaelis, Tomasczewski, and Blaschko. To the last named, who was untiring in his attention, I owe the most convincing information, especially of all the subjects which touch upon the technique of the administration of the remedy and of its clinical applications.

Professor Neisser of Breslau, whose opinion was of great importance to me, was good enough also to give me his eminent advice favourable to the method. For the accomplishment of the task before me the devoted coöperation of Dr. Sachs, the distinguished specialist of Frankfort, was very valuable. I hereby express my thanks to him.

Technique.

Every patient who is to receive the injection of "606" must have been examined previously with the greatest care both from the point of view of his state in general and of his organic integrity. The fundus oculi requires the most minute examination by the ophthalmoscope. The analysis of the urine is indispensable, and only when there is no exhibition of that waste which would preclude the use of the remedy and when the form of the disease is appropriate may an injection be made.

The patient who is to be treated (and this is one of the most important points to be conveyed to the physicians and the public) must be kept in bed during the first two or three days and after that confined to his room during a period varying from six to ten days. These precautions are, moreover, enforced by the watchful care which has to be exercised by the physician both as to the local reactions of the injection and as to the general state of the patient. One must bear in mind that the injection of "606" should not be applied to those attending as out-patients, and that it is the duty of all physicians to refrain from treatment of this nature as regards patients who do not come under this category.

I have no intention of dwelling any longer on the technique of the injection,[1] for my desire is but to furnish physicians with a guide giving the actual indications and contra-indications of "606" and a general outline of the future of the method.

Now I wish to give some of the general indications. The dioxydiamidoarsenobenzol is a yellowish powder contained in ampules in which a vacuum has been created and the manipulation of which, before the injection, requires a certain adroitness. It being always necessary to prepare the injection when about to be used and sterilisation not being possible after its preparation, it follows that the most exacting asepsis must be followed in its manipulation. The instruments, mortars, pestles, glass tubes, pipettes, shaking apparatus, &c., must be rendered aseptic by the spirit lamp flame or by the flame of a Bunsen burner. The different solutions are to be sterilised by the autoclave or by being sufficiently heated. I shall not repeat every time these directions for maintaining asepsis, which are of an equal importance for the various procedures.

1. *Herxheimer's process.*—Average dose, 0·50 gramme. The powder requires careful trituration in the mortar, and a solution of ½ cubic centimetre of 20 per cent. caustic soda has to be added; whilst continuing the trituration, 10 cubic centimetres of water are to be added in small quantities, and the injection is to take place immediately so as to prevent separation and precipitation.

2. *Blaschko's process.*—Blaschko also employs a 20 per cent. solution of caustic soda of 1·225 density, to which he adds about 0·09 gramme per decigramme of prepared powder—viz., 0·36 cubic centimetre for a dose of 0·50 centigramme of powder. The powder has to undergo a long trituration and then he adds from 4 to 6 cubic centimetres of hot boiled water.

3. *Michaelis's process.*—For a dose of 0·50 gramme of the drug from 1 to 2 cubic centimetres of ethylic alcohol is to be poured over the powder in a test-tube. 20 cubic centimetres of distilled and very hot water are to be added gradually with continued stirring. When it is well dissolved, 1 cubic centimetre of "normal" caustic soda solution (40 per 1000) per decigramme of prepared powder is to be added. To the liquid from 2 to 3 drops of phenolphthalein (1 in 200) are to be added. The colour becomes red. Some drops of a normal solution of acetic acid are added until the preparation takes the colour of yellow sulphur. At this moment add 2 or 3 drops of the alkaline solution in order to neutralise the excess of acid, and stop the operation when the upper part of the liquid shows a pink halo.

[1] I will complete these remarks and will give later in the journal La Clinique the description of Wechselmann's process and the technique of intravenous injections according to the process extolled by Professor Ehrlich.

The syringe which is used is one of 10 cubic centimetres capacity, armed with a platinum needle of large calibre of about 6 centimetres in length. Any pattern which can be sterilised will answer the purpose. In Germany the "Record" syringe is commonly used. The seat of the injection is previously washed with soap and water and cleansed with ether. In some clinics the asepsis is completed with a painting of tincture of iodine.

The spot chosen for the injection varies according to the operation: the region of the buttocks, back, inter- or infrascapular region, breast, or the infra-mammary region. The injection can be subcutaneous or intramuscular. The latter is made principally in the region of the buttocks and at spots generally chosen for the injection of insoluble mercury compounds.

I must admit that I have not seen the intravenous injection practised by any German physician. Though Professor Ehrlich recommended it in order, he said, to make use of its particularly rapid action upon syphilitic lesions, he intended it to be followed, however, at the end of two or three days by a subcutaneous or intramuscular injection, the latter being destined to prolong the curative action of the remedy by means of the accumulation of the drug becoming deep-seated in the tissues.

The injection of the substance is made at two periods of time, the same as for the insoluble mercurial injections, in one or two applications according to the quantity of liquid to be injected (viz., from 5 to 25 cubic centimetres) and to the capacity of the syringe.

The injection of "606" is accompanied by some local and general reactions, the importance of which need not be exaggerated, especially when the manipulation is made with great care. Nevertheless, they are sometimes rather violent, and therefore it is necessary to assure the patient that he is in no danger. These reactions are: 1. Pain, often easy to bear, sometimes violent, even very violent, which appears some hours after the injection. This pain shows its maximum intensity in the course of from 12 to 24 hours, and in some very few cases where it is intolerable the application of ice or the injection of morphia will be sufficient to relieve it. Sometimes it is prolonged in a diminished form for several days, and causes thereby a certain degree of functional disorder in the lower limbs with shooting pains. Even slight fibular peroneal paresis has been known to ensue. For a great number of patients the phenomenon implies more a painful embarrassment aggravated by depression than an actual pain, but sometimes it will persist for a long time. 2. The inflammatory swelling is rather similar to the local reactions which are caused by large injections of calomel. It seems to me that the subcutaneous injections, without being more painful than the intramuscular injections, rather favour the appearance of this tumefaction, which is immediate when the vehicle of the medicament varies between 15 and 25 cubic centimetres. This swelling is sometimes accompanied by redness of the skin, and at first sight it would seem as if an abscess was beginning to form, but the palpation of this tumour does not reveal any fluctuation at all. It is consistent, hard, and painful to the touch in general. If no fault in antisepsis or unskilfulness in the operation is committed no complication will ensue.

Fever occurs quite noticeably after the average dose of 50 centigrammes in one case out of four or five. The rise of temperature is most often very slight, especially when the patient has not committed any imprudence. Sometimes the rise of temperature may be altogether insignificant. Consecutive eruptions are rather frequent; generally everything confines itself, as we shall see later on, to a kind of accentuation of the specific erythemata, which are surrounded by a congestive halo, or an urticaria may ensue during the course of two or three days. These eruptions are but rarely of any importance.

Constipation generally occurs; diarrhœa sometimes ensues when a large dose is administered and is often to be found in cases where febrile reaction is violent, with dryness of the throat and other signs of arsenical intoxication. Duhot mentions this as a normal complication following on a large intravenous injection.

Researches on spirochætæ (reaction of Wassermann).—Before forming an opinion of the clinical results that were obtained I was struck with the efficacy of the treatment as attested by the laboratory control. It is indispensable that two laboratory researches are made before each reaction, the search for the spirochæte and the sero-reaction of Wassermann; this is an indispensable complement of clinical observation to ascertain the extent to which the treatment is efficacious. I have seen the spirochætæ disappear at the end of from 24 to 36 hours; but they may remain longer, without, however, being found after six or seven days. Even before its complete disappearance one can see by examination and by the ultra-microscope that its vitality is markedly attacked. The movements of the spirochætæ diminish or disappear, and the refraction, which otherwise is so characteristic of the parasite, passes away. Regarding the reaction of Wassermann, which will allow us to determine and appreciate by its course the regression of infection, it becomes negative in intervals varying from three weeks to two months. The disappearance takes place slowly and progressively, without undergoing the oscillations which I have met with in mercurial cures.

The comparative study of the disappearance of Wassermann's reactions in the mercurial treatment and in Ehrlich's method has not been pursued sufficiently to allow formal deductions to be made on the superiority of one or the other of these methods. It is right to recognise in any case that if the mercurial medication has sometimes given me complete and early negative sero-reactions, yet I have hardly ever obtained this result in a negative and durable fashion until after the strict application of prolonged intermittent mercurial treatment maintained during three or four years.

Evolution of the Syphilitic Lesions Treated by "606."

I propose to pass in review the manifestations which I have seen treated by Ehrlich's method by following the order in which they occur in the different stages of syphilis.

Chancre.—I have seen a number of patients, who were at the time under treatment for one or several genital or extra-genital chancres. The action of "606" seemed to me particularly rapid as regards a case of chancre on the lip which healed in three or four days; the submaxillary buboes were re-absorbed as by magic. I was less struck by the rapidity of the action of the drug on genital lesions. Some of them were clearing up in two or three days and were healed at the end of from five to ten days. Subjacent nodular infiltration, although greatly reduced, still remained. The inguinal buboes in most of the cases seemed to retrocede with some slowness.

The action on the original lesion by "606," taking into account only this first objective manifestation of syphilis, appeared to me, I must say, much less striking than for a number of other syphilitic lesions. This peculiarity had not at all escaped Ehrlich, who informed me of it himself, but as being exceptional. He reported a case to me where the seat of the chancrous ulceration was proof against all healing, and it only gave way after additional use of the mercurial treatment. The presence of the spirochæta persisted up to this stage. This is undoubtedly an unusual case, for generally the disappearance of the spirochæta at the stage of new syphilitic lesions is noticeable, as I have already stated, in an extraordinarily short period.

This mark of a relatively reduced efficiency of "606" upon primary lesions is explained to my mind by the vascular thrombi which to some extent appose themselves between the medicament and its contact with the spirochæte. It is not at all exceptional in ordinary practice to note the same phenomena with mercurial medication, especially when soluble preparations are employed. Soluble preparations act with an undeniably greater rapidity, even when the nodular induration often persists in an abnormal fashion. One must not conclude from these partial and exceptional failures, or from the slow action of the "606," that its efficiency is to be doubted at this stage of the malady. The syphilitic infection, it is true, has already gone beyond the limits of chancre and its bubo-satellites, yet the sero-reaction, almost always negative from three weeks to two months after the injection of "606," proves its sure curative action in an unimpeachable manner on the general infection. The only practical conclusion which can be drawn from this observation necessitates, if a rapid and complete cure of syphilis is to be attempted, a combination, as proposed by Blaschko, of the local treatment of chancre with the general treatment (destruction by the galvano-cautery, and even the local mercurial treatment). It is hardly necessary to state that in this case, when the local mercurial injection and even the general injections can be administered concurrently with

the "606," Ehrlich absolutely forbids the use of any other arsenical preparation such as atoxyl or hectine.

Secondary lesions.—Numerous are the cases of secondary syphilis for which I saw "606" employed. Now, in the first place, I will mention the extraordinarily efficacious action of this preparation on mucous plaques in all localities and of various kinds. The simple mucous patches of the tonsils and of the soft palate, the erosive syphilides or the superficial ulceration of the lips disappear as if by magic from 24 to 36 hours after the injection; not a trace can be found sometimes even 12 hours after its administration. The vulvar and penile syphilides, especially when accompanied by vegetating forms and when soaked for a long time, initiated and fostered by neighbouring suppuration, heal up more slowly, but the action of the drug is still very rapid in this instance. In the practice of Professor Lesser I have seen cases of very extreme syphilis of the vulva which were cured and healed completely in the course of from 8 to 12 days without any other local treatment than simple cleansing baths. The isolated or confluent vegetating syphilides disappear in about the same space of time. The lesions gradually begin to disappear after treatment, sometimes in 24 hours. Some of them disappear 5 or 6 days after the injection. This extraordinary efficiency and rapidity of action of "606" on lesions which are eminently contagious stands out by reason of one important part which this specific is destined to play in the prophylaxis of syphilis. The eruptive lesions of the secondary period give way also very rapidly under the drastic influence of "606." The granular syphilides react more quickly than the papular forms, and still more so than the papulo-granular forms or lichenoids. A certain amount of resistance exists to the treatment of certain skin manifestations of syphilis with "606" as may be noticed when mercury is employed.

The intensive mercurial treatment—namely, the use of calomel or of biniodide of mercury in large doses—seemed to uphold in some cases a comparison regarding intensity and rapidity of action with "606." The disappearance of the lesions in most of the cases was, however, remarkable. I have seen papulo-lenticular syphilides that were disseminated in an extensive form over the body of the patient disappear in less than three days, leaving only a light pink colouration behind.

It is as well to remark here that the injections of "606" cause a reaction on the skin of those patients suffering from secondary specific eruptions which was reported principally by Herxheimer. During the first few days following the injection it is often very noticeable to find macular spots which, when a roseola is in question, will be congested, take a very pinkish colour, augment even in volume, and will sometimes be surrounded by new eruptive macules. When papular syphilides of various kinds are in question the eruptive elements will then be encircled by a kind of areola, or rosy halo which gives the affection an appearance of a sudden aggravation. This additional eruption disappears rapidly, and with it a cure of the specific lesions is obtained. Herxheimer does not consider these frequent yet not always present manifestations as an unfavourable sign for the cure; on the contrary, they are, in his belief, the forerunner of a rapid regression of the lesions.

Now what can be said in reference to the serious secondary syphilides, those which we call early malignant syphilides, pustular, ulcerous, ecthymatous, raspberry-coloured syphilides? Above all, the treatment by "606" is a veritable triumph for these, even if the manifestation of them be single, small in number, or general. It is for affections like these that the healing power and eminent restorative action of "606" is most complete and rapid, and that all the more as the general affections and functional troubles, from which so great a number of patients suffer, become better and disappear as quickly as the cutaneous and mucous lesions are healed. Reappearance of strength, spirits, and activity, restoration of appetite, disappearance of fever and headache, improvement in colour, increase in weight, &c., —such are the phenomena which generally mark the extraordinary recovery of these patients. I have also noted identical successes, although they were slower, for infiltrated and non-ulcerated forms of tuberculous syphilides *en placard*. It seemed to me as well, though Professor Herxheimer is not of this opinion, that certain forms of very local tuberculo-ulcerous syphilides (forehead, wrists, arms, and shoulders) heal up less quickly than the general forms.

By the side of these secondary manifestations, which are nothing more than the lesions of early tertiaries, and upon which the mixed medication (iodide of potash and mercury) shows a very energetic and comparatively rapid curative action, there are other manifestations which are noted for their tenacity and prolonged resistance to all the old treatments. For instance, I may mention deep and extensive inveterate forms of palmar and plantar syphilitic keratosis. I had the opportunity of observing two cases, one in Professor Ehrlich's laboratory itself, the other in the practice of Professor Herxheimer. The first case was completely cured in a relatively short period of time, and in the second case the lesions had almost entirely disappeared in about a week after the injection.

Tertiarism.—The tertiary manifestations do not resist treatment by "606." One can even say that the action of the drug is particularly startling for all ulcero-gummatous forms in this stage of syphilitic affection. Among other examples I will only mention the case of an enormous gummatous ulcer on the leg which was seen in Professor Erhlich's laboratory, and of which more than half was dispersed in five days. It is quite remarkable that the phenomenon of periostitis, which sometimes is so painfully subjacent to the gummatous manifestations, is the first to disappear. In all cases of periostitis it is known that the pains disappear from the first night following the injection.

I must quote here a case under Professor Lesser's care, all the more remarkable as I was able to verify myself from the examination of the patient and the careful study of his chart the extraordinary preventive inefficiency of mercury administered in all its forms: inunctions and injections since the year 1900. It was a case of two enormous contiguous gummatous ulcers developed in the centre of the dorsal surface of a tongue having already undergone the commencement of a superficial sclerotic degeneration. The pain resulting from this prevented the patient taking any food except in liquid form. Now this affection, of which an excellent coloured photograph admirably reproduced the lesion that was still intact eight days before my visit, was totally and radically cured at the time I made my examination. There remained only a linear fibrous scar towards the middle line; the rest of the tongue had regained its normal suppleness; all pain and functional trouble had disappeared. In the same way in Professor Herxheimer's clinic a gumma on the roof of the mouth to which no local treatment had been applied had been completely cleansed and its edges were well on the way towards healing three days after the injection.

It does not seem necessary to follow this up by speaking of more striking cases. However, I cannot pass over in silence a very grave case of gummatous ulcerative pharyngeal and peri-laryngeal syphilis under the care of Dr. Michaelis, lesions which put the patient's life in serious danger, yet were totally cured in a few days. More striking and perhaps more significant still are the two following cases observed in Dr. Michaelis's clinic. They relate to tertiary affections of an unusual variety, of little danger in themselves, it is true, but very offensive to the patient, and on good grounds said to be incurable, or at least ameliorated with difficulty in the majority of cases. He had to deal with an ozæna from which the repulsive smell disappeared 48 hours after the injection and which was radically cured three weeks later. This fact may be compared with the extraordinary results attained by von Zeissl and Duhot in the treatment of a diffused hypertrophic "syphiloma" on the nose and upper lip. The second patient was stricken with a chronic syphilitic arthropathy which had resisted all treatment but which yielded to the really miraculous action of "606."

The treatment of visceral syphilis constitutes one of the most interesting points in this branch of therapeutics, and will, no doubt, become more so, but the relative scarcity of cases and the difficulties encountered in their diagnosis and their observation place them amongst those least studied up to the present. Mention must be made nevertheless of cases of syphilitic icterus cured in less than a week by Wechselmann, and of a case attended to by the same doctor of ulcerative syphilis of the rectum rapidly cured with a very slight stenosis supervening which did not inconvenience defæcation.

As regards lesions in visceral syphilis, such as hepatic or renal syphilis, Ehrlich's treatment may be applied to them with exceptional benefit, and I can already see a fine result

accruing in one of Dr. Bensaude's patients afflicted with a serious recurring syphilis of the stomach in spite of the mercurial treatment. But in all these cases of visceral syphilis it is indispensable that a very close clinical examination and the investigation of Wassermann's sero-reaction permit one to conclude with certainty as to organic lesions of a syphilitic nature. We shall see, in fact, further on that all visceral lesions of another nature constitute a formal contra-indication.

My attention has often been attracted and held by the application of "606" to cases of syphilis of the nerves, but before starting on this subject I will describe what I have witnessed as to lesions in ocular syphilis. The amelioration of cases of conjunctivitis, choroiditis, and iritis that I have seen under treatment was indubitable, but the treatment was of too recent a date to enable one to estimate definitely the result which was announced as excellent. Gluck, however, reports a case of iritis with synechia in which the photophobia had disappeared on the second day, and where the eye had returned to the normal after eight days. He brought about likewise the cure of a double iritis, but after a resistance lasting three weeks. The same author also mentions a parenchymatous keratitis which was cleared after two days, and visibly ameliorated, but incompletely cured when the patient left the hospital 21 days after the injection.

In spite of the formal contra-indication established by Ehrlich himself in the presence of certain nervous manifestations Dr. Wechselmann quotes at least five cases of syphilis of the central nervous system, of which two are of recent date, which underwent treatment without harm by "606." I have myself in Dr. Michaelis's practice assisted at the cure of one of these lesions in cerebral syphilis presenting nevertheless a threatening aspect, the symptoms of which were soon reduced to a few attacks of headache. A woman afflicted long since with syphilis showed, amongst other pre-ataxic lesions, a commencement of papillary atrophy. The injection of "606" as stated by the ophthalmologist who had closely inspected the state of the eye, had considerably improved the acuity of vision.

The formal interdictions of Professor Ehrlich himself and the echo of quite recent accidents following on the use of "606" as regards syphilis of the nervous system oblige me to show a great deal of reserve as to the therapeutic successes attained in these conditions. Thus Dr. Fraenkel and Dr. Grouven announced on August 25th a case of death ensuing two hours after the intravenous injection of a dose of 40 centigrammes on a young man afflicted with a cerebral gumma. One of the first questions that I put to Professor Ehrlich referred to the case of one of my young patients stricken with syphilis of the central nervous system barely eight days after syphilitic infection. The mercurial treatment having only given partial results, I inquired as to the possibility of applying an injection of "606." Professor Ehrlich, in opposition to my wish, absolutely forbade the use of his remedy. I gather that until a distinction based on experience can be made with real security between patients afflicted with the various forms and localisations of syphilis of the nerves, it is advisable to show a great deal of circumspection. It is quite different with a class of patients who appear to derive great benefit from this method when they enjoy ocular integrity. I am referring to the tabetic cases at the very beginning of the affection.

Hereditary syphilis.—The idea of applying the Ehrlich treatment to hereditary syphilis was so natural that a special study was made of it from the commencement. The substance was injected without harm in several women who were pregnant. Gluck, however, mentions a case where there was cessation of the heart beats in the fœtus shortly after the injection. I have myself seen a baby a few days old literally covered with syphilitic pemphigus, and who had received from Dr. Michaelis an injection of 10 centigrammes of "606." Commencing from that day, its weight had increased progressively to a considerable extent, and the cutaneous lesions and buccal symptoms had almost entirely disappeared.

I must call to mind here the urgent recommendation made to me by Professor Ehrlich on this point. According to him babies should not receive more than from 3 to 5 centigrammes of his preparation. Even then he considers this dose as fatal for the majority of them if one does not take the following precaution based on a very curious fact of observation. A baby had been completely cured of its apparent syphilitic lesions by taking its mother's milk, who had herself been subjected to an injection of "606." Professor Ehrlich prudently concluded from this that it was advisable to have recourse for some little time to the beneficent action of the mother's milk, who had been previously injected, before proceeding to inject the baby itself.

No opinions have yet come to my knowledge bearing on cases of tardy hereditary syphilis.

Relapses.—I have not been able to verify any case of relapse myself, but some observers have remarked on them. This phenomenon, as pointed out by Wechselmann, is explained by the fact that the spirochæta, contrary to the trypanosoma, is only a parasite of the blood in a very transient manner, and leaves it, setting up isolated lesions in different parts of the body. These are apt to become active again and to return to the virulent state after some considerable time. This is the reason, moreover, why positive sero-reactions follow on negative sero-reactions at variable intervals.

Non-success.—Does Ehrlich's method, properly speaking, show cases of complete non-success the same as mercury does apart from its use in parasyphilis, where it seems to have failed up to the present? I have not been told of any instance, but I have witnessed a case under Professor Lesser's care where a man was attacked with ulcerative syphilis on the cranium and face, and the lesions showed no modification about 10 days after administering the injection. The assistant who examined him thought, from his observation of the persistency of the tumour formed by the injection, that a kind of encystment of the substance had been formed. It is probably in order to avoid this trouble that Dr. Michaelis applies a vigorous massage to the injected part for at least 10 minutes after having given the injection. Professor Ehrlich also told me of a case where a very tardy cure seemed to him to be due to the previous administration of arsenical preparations.

To sum up, I would conclude:—

1. *That the Ehrlich method up to the present is contra-indicated* as regards elderly men; for all persons having non-syphilitic visceral lesions—renal, cardiac, hepatic, splenic, pulmonary, and vascular affections, such as advanced aneurysm of the aorta; again particularly as regards patients who have not a normal condition of the fundus oculi. Towards patients who suffer from a severe syphilitic affection of the brain, such as recent hemiplegia, acute or sub-acute meningo-encephalitis, it is necessary to observe the utmost caution, and, awaiting more ample information, to intervene only in very grave or desperate cases when mercury has ceased to be efficacious. Constitutional weakness and cachectic conditions are not always contra-indications.

2. *That the Ehrlich method is formally indicated:* (*a*) for all patients where the lesions do not yield to mercury; (*b*) when a relapse takes place following immediately on an apparent cure with mercury; (*c*) in cases of repeated relapses; (*d*) when a total mercurial idiosyncrasy contra-indicates the use of all mercurial forms of treatment; (*e*) for all patients attacked with malignant syphilis, with secondary or tertiary syphilides deeply destructive and mutilating, or most serious on account of their position and the disorders or dangers that they occasion; (*f*) again, for attacking syphilis when the chancre first appears, on condition that one adds to this the initial treatment of the spot attacked by an intermittent and prolonged mercurial course.

3. *That in every other case* one may, according to the circumstances and fitness independent even of the infection, use either Ehrlich's method or the old mercurial methods. I think, as do a number of writers on syphilis, these two methods of treatment assist and supplement each other in a certain number of cases. A long comparative study of the two kinds of treatment, of their advantages, their inconvenience, and their efficiency, will allow one to determine within narrower limits the precise indications for one or for the other.

Future of Syphilitic Persons treated by "606": Importance as regards Prophylaxis.

A definite cure, and under one treatment, is it a thing already realised or realisable? This question of the definite cure of syphilis by "606" is one of those which have thrown most confusion on the real value of Ehrlich's discovery. In debates brought to the knowledge of the public at large the influence of this therapeutic treatment on syphilitic manifestations has constantly been mixed up with its action on

the definite evolution of the malady. The incontestable superiority of this method in the treatment of a great number of conditions has just been pointed out. Let us discuss now its action on syphilitic infection itself.

One cannot help being attracted by this admirable conception of Ehrlich of the *therapia sterilisans magna*—that is to say, of this sort of knockdown blow given to the malady at the very moment of its inception. But how can one demonstrate this almost miraculous action that we so ardently desire, that we believe to be perfectly realisable, but which we have only partly seen as yet? We have at our disposal three available methods: animal experiments, the reaction of Wassermann, and the clinical evolution of the malady. Experimenting on animals is subject to some objections. One cannot help being struck with the difficulty in generalising spirochætæ in an animal, whilst in the case of man the spreading of the organism takes place with such rapidity that the excision of the part first involved, however early it may be, is always too late. Certainly we have to admit that almost all the spirochætæ are destroyed by the first injection. We know, however, that a second one is sometimes necessary to cure an immediate relapse. In these circumstances, how can one help fearing that some of these micro-organisms may escape total destruction and establish themselves in different parts of the organism in such a way that they are fortified against the therapeutic action of the drug? Truly, Wassermann's reaction will be a valuable indication for us as regards the degree of virulence in the infection, but we must bear in mind that this reaction only gives indications for a variable time and that, on the other hand, negative results have sometimes coincided with localised tertiary outbreaks.

There now remains the clinical evolution of the malady in patients treated by "606." A certain number, a minority it is true, of these patients certainly are not cured by one injection only, since several doctors have had relapses under observation, as I have already related above. The question remains as to whether we have any knowledge of syphilis definitely cured. Yes, certainly, and in an immense majority of cases. But have we not all seen how syphilis that has been ignored or misunderstood, and consequently not put under treatment, will remain quiescent during the first stages of its evolution and remain dormant during periods of 10, 20, or 30 years, and even during one generation and will come to life again in the light of that most dangerous malady of the nervous system—general paralysis? How can we establish clinically a fundamental difference between this kind of natural immunity and that which we can apparently obtain from Ehrlich's method, or those which are the habitual consequence of an intensive mercurial treatment?

No writer on syphilis has ever thought that however striking the action of mercury may have been (and cases are not rare) on the initial lesions of the malady, a definite guarantee has resulted therefrom against any early or late relapse. It is, on the contrary, to the prolonged and methodically regulated action of mercury that we owe a large number of definite cures. Why give to "606," in spite of its splendid promises, the definite credit that we have refused to mercury, and neglect henceforth the guarantees that we assume from the fundamental treatise of syphilis? The future, but a far future no doubt, will bring to us on this point the elements of appreciation which at present are wanting. But if we are now, and shall be kept long, deprived of an infallible criterion for appreciating the definite curative value of this medication, let us not despair of realising some day that this wonder may be accomplished by Ehrlich, for this task is not beyond his lively conception. In short, if nothing is more difficult than to appreciate the value of a drug this difficulty becomes even greater when applied to a malady like syphilis, of which the particularly variable advance, the frequent remissions, and spontaneous cures constitute so many causes capable of leading into errors the wisest clinical practitioners.

If it is demonstrated some day that Ehrlich's curative method can do without any help, in the meantime, at least, one is permitted to associate with this method those which have up to the present borne the brunt of the fight against syphilis so valiantly and so successfully. One cannot without injustice and imprudence forget and despise the admirable preventive services due to prolonged intermittent mercurial treatment extolled with such high and indisputable authority by Professor Alfred Fournier, and I firmly believe that the security of patients will find its best guarantee in the fruitful alliance of the two therapeutics.

I can only repeat here my statement made above. Ehrlich, who is opposed to the parallel use of other arsenical preparations, is in no way opposed to the simultaneous or consecutive administration of "606" and of mercury. From this very moment, however, the curative and preventive rules towards the individual of Ehrlich's method are not the only ones that one should consider with cheerfulness. It is equally certain that its action will preponderate in the struggle against the propagation of syphilis. We shall owe to it a certain prophylaxis due to its action, so constant, so rapid, and so durable on the mucous patches and in general on all the erosive or ulcerative lesions from which infection is disseminated. We may possibly see likewise, thanks to Wassermann's sero-reactions, the rapid cures, and this from one application, of syphilis in prostitutes under observation. The discovery of a latent syphilis necessitating an injection of "606" would assure at least for some considerable period absolute innocuousness, whilst at the present time the protective measures are unfortunately too often tardy, and therapeutic intervention of difficult application because they are too frequent.

Will Ehrlich's method give us any new data toward the problem, often a very delicate one, the question of the marriage of syphilitics? The conditions at present decreed are based on the frequency and intensity of relapses, the length of the affection, and also on duration of the treatment. As regards "606," we may venture to hope that the veto resulting from the circumstance of malignity and of relapses of the evil will no longer have a reason for being exercised. On the other hand, the question of duration will still have to be considered. This arises from the state of uncertainty we are in as to the definite curative action of this remedy, and the removal of the initial stage of the malady must for the present remain our best security. What treatment should be insisted on? Sero-reaction renewed at fixed intervals can by its negative results justify to a certain extent the absence of all treatment previous to the injection of "606," but we must not lose sight of the fact that negative results have sometimes been compatible with tertiary outbreaks, and under all conditions *it would always be better to exact the extra precautions of mercurial treatment.* For the somewhat numerous patients who are not strictly conformable to the rules of preventive mercurial treatment, but as regards whom one cannot say that marriage is forbidden because their syphilis is of old standing and has not caused lesions for a long while, it would be prudent to advise as an additional security the injection of "606" a few months before their marriage.

May one hope that the therapeutic application of "606" will soon emerge from the phase of a study in order to take its place in the domain of medical practice? This remains to be decided by the German master, and he alone will be the judge, and a good judge, of the opportune moment. Surely we may at once proclaim that "606" is a remedy of remarkable power; but the subject of contra-indications, not perhaps completely dealt with by recent experiments with the famous remedy, and therefore still a little obscure, inevitably leads to a certain number of disappointments.

How can we wonder that a remedy possessing such strong activity and curative powers should sometimes bring about troubles, and even cause some danger to accrue to certain individuals and to certain organisms? An exemption to the contrary would be at least singular, and there is all the less reason for blaming it for the contra-indications levelled against it by the author himself since mercurial preparations themselves are not proof against this reproach, although people have in a peculiar way, I might almost say ridiculously, exaggerated their maleficence. It is true that inexperience and want of caution have often been solely to blame in such cases, but it is but wise to foresee their repetition when dealing with "606," and the best warranty one can have against these compromising elements is to make no use of the valuable remedy until the indications and contra-indications have been thoroughly and definitely demonstrated. It is as well to foresee the pessimistic interpretations of this method that

failures or accidents might occasion. But my absolute conviction is that it will overcome all resistance, coming from whence it may, in the same way as its illustrious predecessors, radio-therapeutics and sero-therapeutics themselves paid their experimental tribute.

Whatever may be the fortunate future of Ehrlich's discovery, one cannot withhold an unreserved admiration from this sympathetic *savant* whose whole scientific career is a model and an example of ingeniousness, of logic, and of perseverance. No link is wanting in the unbroken chain of his experiments all directed towards one end. From the very beginning of his studies Ehrlich set himself the task of determining the elective affinities of certain chemical substances towards the various organic tissues. After having shown us the affinity of the granulations in blood corpuscles towards certain colouring matter, after having proved the existence of chemical substances which are fixed by the living micro-organisms in the human body, he discovered this elective action shown by certain arsenical compounds towards spirilla. We can state therefore that the discovery of "606" is not due to mere chance, but, on the contrary, is the ultimate result of a whole series of researches conducted with scrupulous care and admirable certainty of deduction. It is better than the spontaneous creation of a purely intuitive genius: it is the crowning point of a splendid scientific career and the work of a lifetime.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON PSORIASIS FROM A BACTERIOLOGICAL POINT OF VIEW.

BY A. D. SERRELL COOKE, M.B., CH.B. EDIN.

THE causation of psoriasis has for some considerable time been a source of dispute among dermatologists, as, while some claim that the disease is neuropathic in origin, others maintain that the disease is parasitic in nature. It was from the latter point of view that a research was undertaken in the laboratory at St. John's Hospital, Leicester-square, by the writer in conjunction with the bacteriologist of that hospital. On histological grounds it seemed reasonable to suppose that if a micro-organism were to be constantly found it would have to be searched for in the rete and papillary layer of the skin in active psoriatic lesions; and at the outset it may be stated that in all the cases of psoriasis coming under observation, to the number of 20, a bacillus was found to be constantly present. This is the more interesting, as, so far as can be ascertained, no bacillus has been before described in association with psoriasis.

Lang[1] believed he had found a fungus, and this or an apparently similar one was found by others, including Wolff,[2] Eklund,[3] and Beissel.[4] Ries,[5] however, showed that the alleged fungus was an artificial product consisting of eleidin. Micrococci were observed by Angelucci[6] and De Matei, while Unna described morococci. Crocker[7] found minute circular bodies with central dark spots, loosely clustered and in dense masses.

Cases of alleged communication have been recorded.[8] The disease has been known to occur after vaccination on the vaccinated areas,[9] while Lassar,[10] Campana,[11] Tommasoli, and others are stated to have communicated the disease to animals by rubbing in the scales, blood and lymph of an infected human. Destot[12] succeeded also in successfully inoculating himself from a case occurring after vaccination.

In the present research, almost invariably in all the 20 cases which came under observation, the following organisms were to be found—viz.: (1) short stumpy bacilli; (2) very large cocci, tending in culture to take the arrangement of staphylococci, and also to occur in groups of four; (3) somewhat large cocci, tending in culture to take the arrangement of staphylococci, and also to occur in pairs; and (4) cocci, of the type of staphylococcus aureus and albus. Frequently also were to be seen cells resembling yeast cells or the so-called bottle bacillus of Unna; on one occasion was seen a structure which appeared to be a fungus with spores; on another were seen bodies resembling those described by Crocker; and on yet another occasion a short, somewhat slow growing spore bacillus was seen and grown in culture. Without commenting on the findings in all these 20 cases of psoriasis, it would be as well to point out that they would appear not only to correspond with the collected findings of others in psoriatic lesions, but also, in addition, to show the constant presence of a short stumpy bacillus. This short stumpy bacillus, which was invariably present, has the following morphological characters. It is a short, thick, stumpy rod, measuring $1 \cdot 75\,\mu$ in length, with some tendency to arrangement in pairs; it is non-motile, stains readily with aniline dyes, and is Gram-positive. It is an aerobe and a facultative anaerobe, growing well at 37° C.; on agar a white glistening growth occurs after 18 hours; on broth the organism grows very slowly, producing some general turbidity; on Fleming's oleic acid glycerine agar medium a growth is obtained similar to that on ordinary agar; on neutral-red glucose agar a thick, somewhat creamy growth is obtained after 18 hours. On Sabouraud's medium no growth was seen, either aerobically or anaerobically, after a period of incubation at 37° C. lasting two weeks. On other culture media the following results were obtained—viz.: (1) peptone water, slight general turbidity; (2) glucose peptone water, acid, no gas; (3) lactose peptone water, *nil;* (4) mannite, *nil;* (5) dulcite, *nil;* and (6) litmus milk, slightly acid with some curdling.

In conclusion, it may be stated that the question of the communicability of psoriasis and the effects of vaccine treatment are now being investigated. When these and other points have been gone into, and observations have been completed, a full and detailed account of the research will be published.

NOTE ON A CASE OF HYSTERICAL DYSPRAXIA.

BY TOM A. WILLIAMS, M.B., C.M. EDIN.,
FOREIGN CORRESPONDING MEMBER OF THE NEUROLOGICAL AND PSYCHOLOGICAL SOCIETIES OF PARIS; NEUROLOGIST TO THE EPIPHANY DISPENSARY, WASHINGTON, D.C.

A NEGRO male, aged 30 years, was seen by me with Dr. Randolph at the Garfield Hospital, Washington, two days after admission for acute intoxication with alcohol. For 24 hours he was severely delirious, refusing to stay in bed and yelling violently. He refused nourishment and medicine, and had to be restrained with a sheet. Even when he was calmer he could give no coherent account of himself, but admitted drinking heavily. He described terrifying hallucinations, and would gaze fearfully into one corner of the ward, where he saw fierce animals. He also felt creatures as if crawling up his arms under the skin.

The day before I saw him, while he was talking with Dr. Randolph in a disconnected fashion, his right arm slowly was raised from the bed. It went tremulously, as if with great difficulty, as it were resisting a strong restraint (dyspraxia). After about half a minute the arm dropped passively. The patient appeared quite unconscious of this movement, neither facial expression nor words indicating that he was aware of it. On being asked to raise the right arm the performance was repeated while he watched it in a detached manner. When told that the left arm could not be moved he repeated the performance with it (negative suggestibility). In both cases the arm was fully extended, and he appeared unable to bend it. But on being told that

there was nothing the matter with the arm he bent it quite promptly and naturally (suggestibility). When asked to protrude his tongue he did so promptly, but could not retract it, although he appeared to make an effort (dyspraxia). Even when sharply ordered to do so he only succeeded in violently contorting the face with a tremulous spasm, the tongue remaining protruded. But on being quietly told that there was nothing wrong with his face, and that he could draw in his tongue quite easily, he immediately did so, and placidity returned to his countenance. Other similar observations were made, but were not noted.

The next day when I first saw him the phenomenon did not persist; and he was no longer violent, and was rational, although the hallucinations had not quite disappeared. He was discharged well the next day.

It is unfortunate that more complete tests of the patient's praxis were not made; but the two incidents related are clearly dyspraxiæ of a most ordinary kind. Neuronic intoxication is the most likely genesis of the disability. But it is evident that organic disability was only partial; and required only a stimulus of the right quality to excite the mechanism of eupraxis.

In this case the stimulus needed was suggestion, as the history clearly shows. The minimising of the apparent difficulty of bending the arm and withdrawing the tongue was a pure suggestion, conveyed by the matter-of-fact attitude of the physician and his quiet tone. In this respect, the symptoms conform to the second postulate of Babinski's definition of hysteria—viz., "Removeable by suggestion-persuasion." The first postulate of Babinski's definition—viz., "Producible by suggestion"—was not ascertained; as when I first saw the patient the symptoms had disappeared, although his suggestibility was still perceptible, as is so frequently the case in the period of post-alcoholic intoxication.

In view of the psychological mechanism governing the suggestibility of post-alcoholic intoxicative states, it would not be surprising to find that hysterical dyspraxia of this type will be quite commonly found when such patients are explored.

Washington, D.C.

NOTE ON A CASE OF APICAL PNEUMONIA WITH MENINGEAL SYMPTOMS.

BY G. H. PRIDHAM, L.R.C.P. LOND., M.R.C.S. ENG.

LOBAR pneumonia in children having an onset which markedly simulates meningitis is, I suppose, not very uncommon. It seems to me from the following case that this occurrence might be explained on a purely anatomical basis, involving the conception of an actual attack of the membranes by the specific organism.

The patient, a previously healthy male, aged 3 years, had a sudden onset of vomiting in the night, accompanied with severe earache on the left side. When I saw him at 11 A.M. the face was flushed but there was no rash. The temperature was 103° F., and the pulse proportionately rapid. The breathing seemed natural and the alæ nasi inactive. There was a little tenderness over the tip of the mastoid bone on the left side, but earache was not then complained of. No previous discharge had been noticed from either ear. Examination of the lungs revealed no adventitious signs. On looking at the throat the pharynx was reddened, the blush extending on to the tonsils. I thought the case to be one of tonsillitis and treated it accordingly. On the next day the boy had a fit, which was followed by head retraction, drowsiness, and twitching of the extremities. The earache was again complained of, and he constantly put his hand up to the left ear. The temperature remained high. Suspecting acute otitis media, I sent him into hospital in case surgical procedures should be required. On examining the drum, however, no bulging was seen. The breathing becoming more rapid, soon afterwards, on auscultation in the right axilla, a patch of consolidated lung became apparent on the third day of the illness. The crisis occurred two days later.

That the middle ear on the left side was inflamed, though not ending in suppuration, I think to be undoubted from the symptoms present. The mucous membrane lining the middle ear is in direct continuity with the naso-pharynx by way of the Eustachian tube. The trachea and bronchi provide an easy path for direct extension to the lung of infection in the naso-pharynx. In this way a continuous tract extends from the middle ear to the lung. Post-mortem examinations on those dying from pneumonia show the bronchial mucous membrane to be red and inflamed. There are several ways for direct extension of the inflammation in the ear to the membranes of the brain. These include lymphatics and the sheaths of the facial and auditory nerves. Lastly, the petro-squamosal suture is unclosed in quite young subjects (Box and Eccles's "Clinical Applied Anatomy").

Grantham.

NOTE ON AN UNUSUAL CASE OF LIPOMA.

BY J. BARRÉ DE W. MOLONY, M.B., CH.B. EDIN.,
LATE HOUSE SURGEON, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

I AM indebted to the courtesy of Mr. Joseph Cunning for permission to publish these notes.

A male child, aged 4½ years, was admitted to Victoria Hospital, under the care of Mr. Cunning, with the following history. Two months before admission a swelling of about the size of a hazel nut had appeared under the left nipple. The swelling had gradually increased in size without causing pain, until it had attained the size of a walnut.

Examination showed a rounded tumour of the size of a walnut just below, and external to, the left nipple. The skin over it was normal in appearance and freely mobile. The surface of the tumour was smooth and its consistence elastic; it was fixed, and there was an impulse on coughing. The child was not in very good condition and there were signs of early tuberculosis at the left apex. A provisional diagnosis of cold abscess was made.

Operation.—A transverse incision was made over the tumour. On dividing the deep fascia a smooth, rounded portion of a lipoma was found projecting between the ribs like the head of a stud through a button-hole. The central portion of the "head" had completely separated the fibres of the external intercostal muscle and had come to lie directly under the deep fascia. The neck of the tumour forced the ribs apart to a distance of 3 centimetres. The base of the tumour, which lay behind the ribs, formed three-fifths of its whole bulk, and was lobulated. One lobule extended outwards between the intercostals for a distance of half an inch. The surface of the tumour nearest the pericardium was rounded. The tumour was easily shelled out.

The tumour had evidently arisen between the intercostal muscles. As it increased in size the anterior portion had been slowly pushed through the external intercostal. Possibly in time the posterior portion, aided by intrathoracic pressure, would have made its way between the separated ribs, and the whole tumour have come to lie in front of the external intercostal muscle.

St. George's Hospital.

THE RADIUM WATERS IN THE JOACHIMSTHAL.—The Austrian Government has published a report upon the official observations made on the radio-active waters in the Joachimsthal bath establishment. 209 cases were treated, the water being used both for bathing and for drinking. Of these, 169 cases are reported as having been improved and 40 as having undergone no improvement. In the first category are cases of rheumatism, uric acid arthritis, neuritis, neuralgia, and of lymph deposits of various kinds, but none of the cases of carcinoma or new formations or of essential disease of the spinal cord or auditory apparatus or of general wasting appeared to have been benefited. In cases belonging to the former category the radium water treatment compares favourably with that by electricity, hot baths, mud baths, massage, &c. Probably the dosage is of importance, though further observations are needed to show how far treatment is to be carried in order to stimulate the vitality of the cells without overstepping the mark and running the risk of paralysing or destroying them. In order to allow of a much more extended use of these waters orders have been given for the erection of a Kurhaus with 60 separate baths, all of which will be supplied with radio-active water by means of a system of pipes. A medical director will also be appointed.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Use of Belladonna in Dyspepsia.

A MEETING of this section was held on Nov. 22nd, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. F. CRAVEN MOORE and Dr. L. KILROE communicated a paper on the Use of Belladonna in Dyspepsia, in the course of which they declared that clinical experience having established to their satisfaction that the administration of belladonna led to a definite amelioration of the subjective manifestations of certain types of dyspepsia, it was decided to conduct a systematic investigation into the action of this drug on the functional activity of the stomach in a series of consecutive cases, both with and without manifestations of gastric disorder. The results of this investigation confirmed and amplified the earlier observations of Riegel, in showing that belladonna exerted a definite inhibitory effect on the secretory activity of the stomach. The administration of this drug along with, or some short time previous to, a test meal was associated with a well-marked diminution of the acid and peptic values of the stomach contents; this effect was generally greater in such pathological conditions as were associated with hypersecretion, but still obtained in conditions of hyposecretion. The effect of the administration of belladonna on the volume of the stomach contents was but slight, and that variable; but whilst by this method it would appear that the drug influenced but little the emptying of the stomach, more recent radiographic observations led to the belief that it exerted an influence in inhibiting and relieving spasmodic contractions.

Dr. W. H. SWAFFIELD suggested that the different amount of absorption of belladonna in different individuals might account for some of the variations in the results.

Dr. A. F. HERTZ said that the paper confirmed his clinical experience of the value of atropine in the treatment of the conditions under discussion.

Dr. NATHAN RAW agreed that belladonna was of the greatest value in some forms of dyspepsia.

Dr. H. FRENCH pointed out that in the treatment of bullous dermatoses, when other remedies failed, small doses of belladonna were beneficial, and raised the question whether belladonna modified the secretion of the alimentary canal and influenced some toxic origin of the condition.

Sir JOHN BROADBENT observed that in cases of spasm there was also dilatation of the stomach in the vast majority of cases of duodenal ulcer.

Dr. KILROE said that in certain cases of spasm associated with hyperacidity definite clinical results were obtained, and even in a few cases of carcinoma great relief was obtained by the administration of belladonna.

The PRESIDENT asked if the patients were permanently benefited by belladonna or were more or less dependent on its continuous use.

Dr. MOORE, in replying, said that the absence of lasting effect was obvious, but that occurred with other drugs. It was by keeping the local conditions well within the normal limits that they were enabled to overcome the vicious circle and in that way belladonna was a drug of great value.

PATHOLOGICAL SECTION.

Dried Mouse Cancer.—Acute Ulcer of Stomach.—Atypical Chloroma.—Bacillus Typhosus.—Method of Mounting Mosquitoes.

A MEETING of this section was held on Nov. 15th, Dr. W. S. LAZARUS-BARLOW being in the chair.

Mr. S. G. SHATTOCK and Mr. L. S. DUDGEON, in describing experiments with Air-dried Mouse Cancer (which were carried out at the Imperial Cancer Research) observed, in confirmation of Jensen's original statement, that the simple drying of cancer pulp in the air at the body temperature was lethal to the cancer cells. No growths could be raised from such material after it was remade into pulp with salt solution and inserted subcutaneously into other mice. That was one factor in preventing the transference of carcinoma from one person to a second by means of carcinomatous débris. In one of their experiments a minute portion of the material remained half dried, and when the whole was remade into a pulp and inserted beneath the skin of 12 mice growths appeared in three. There was extremely little evidence that carcinoma was ever an air-borne disease as were certain of those due to bacterial infection. The authors had sprayed cancer cells suspended in salt-solution into the mouths of mice, the process being repeated more than once, but so far with a negative result. Osler's statement that primary carcinoma of the lung was particularly common amongst the Schneeberg cobalt miners was worth bearing in mind; there the pneumonokoniosis doubtless prepared the way for the other disease. The remarkable vitality of the cancer cell in the undried condition, however, showed that the possible infectiousness and contagiousness of cancer could not be safely ignored. Extending their observations, the authors found that the subcutaneous insertion of air-dried carcinoma produced no prophylactic immunisation to the growth of a subsequent graft, even if that insertion was repeated. That accorded with the results obtained invariably at the Imperial Cancer Research, which showed that dead cancer tissue, whether killed by radium or other means, was powerless as a prophylactic. Neither did the insertion of air-dried carcinoma produce any curative immunisation towards the growth of a graft previously made. The use of a centrifugalised extract (the material being first ground with glass) was similarly inert. By the method of rapid centrifugalisation the whole of the débris was got rid of from an extract in a very rapid manner, a method quite as effective as the use of filter and press. If that extract was used prophylactically the growth of the subsequent grafts, instead of being retarded, in fact was accelerated—a hypersensitiveness was induced. The same result had been obtained by Dr. Haaland from the use of pressed extract.

Dr. CHARLES BOLTON read a paper on the Influence of Diet upon the Formation and Healing of Acute Ulcer of the Stomach. He considered that the theory with regard to the part played by the gastric juice in the production of gastric ulcer received further confirmation, because ulceration was the more rapidly produced in proportion as the gastric juice was allowed a longer period of contact with the wall of the stomach. The epithelium grew over the base of an ulcer more rapidly when the animal was given a milk diet than when it was given a meat diet. In the case of a milk diet the base of a moderately sized ulcer was usually completely covered by the twentieth day, whilst in the case of a meat diet the same sized ulcer would in most cases be uncovered in the centre at that time. Frequently in the case of meat-fed animals the ulcer was completely uncovered on the twentieth day, the granulation tissue of the base of the ulcer having become necrotic. Such an ulcer might be only one-fifth of the size of the original ulcer owing to the contraction of the fibrous tissue in the base although healing had only commenced at the edge. In the treatment of a case of ulcer of the stomach the following principles should be observed: during the early stages of the healing of acute ulcer the patient should be given a food which did not stay long in the stomach and which does not excite a copious flow of gastric juice. The period of treatment in bed should be at least three weeks. The starvation diet of the older physicians was not necessary, because the general nutrition suffered too much and because ulcers healed well on some diet such as the above. In the case of acute ulcers which were extending or chronic ulcers, healing could not be expected to occur in three weeks, because the ulcer must first be got into a suitable condition for healing, and then, owing to its size and thickness, the healing must take some weeks longer to be completed. So that the treatment in bed was to be conducted like that of simple acute ulcer, but extended over a period at least twice as long. Since in many cases of gastric ulcer there was hyperacidity of the gastric juice, and when the gastric juice was acting destructively hyperacidity increased that destructive tendency, that high degree of acidity should be controlled by the administration of alkalis. That was not so necessary in acute ulcer as in the more chronic forms, because the few estimations that had been made of the gastric secretion in acute ulcer showed that it was not hyperacid, and he had found experimentally that the effect of acute ulcer was to

diminish the secretion in the early stages, and that the latter became normal as the ulcer healed.

Mr. A. C. D. FIRTH and Dr. J. C. G. LEDINGHAM communicated a paper on Atypical Chloroma. The authors observed that during the last few years the occurrence of certain forms of chloromatous growth differing widely from the typical picture of chloroma had led to considerable modification of their views regarding the position of that disease as an independent entity, and there appeared to be an increasing tendency to bring it into line with the primary diseases of the hæmopoietic system, and especially with the acute leukæmias. In its typical form chloroma was a disease occurring mostly in young subjects and characterised by the presence of green tumour-like infiltrates connected principally with the periosteum of the bones of the skull, sternum, ribs, and vertebræ. The blood changes described in various cases varied considerably, but the differential blood picture had been found to resemble that of the acute leukæmias which might or might not be associated with any very marked increase in the total leucocyte count.

Dr. C. H. BURTON BRADLEY (Sydney) communicated a paper on the Biological Characteristics of Bacillus Typhosus, with especial reference to the Fermentation of Dulcitol and Arabinose. He concluded that the fermentation reactions of bacillus typhosus were identical up to the fourth day. Bacillus typhosus ferments glucose, mannitol, galactose, and sorbitol with the formation of acid within 24 hours. Dulcitol and arabinose were fermented more slowly, acid being produced usually during the second or third week. Lactose, saccharose, dextrin, inulin, amygdalin, salicin, raffinose, and erythritol were not fermented. Gas was never produced by bacillus typhosus. Litmus milk was turned faintly acid generally within 24 hours and remained thus permanently. The time taken to ferment dulcitol or arabinose varied widely even in the same culture tested repeatedly and also amongst daughter colonies from a single plated culture. The time taken by a given strain of bacillus typhosus to ferment dulcitol or arabinose was very markedly quickened for that strain by a sojourn in media containing dulcitol or arabinose respectively. Within certain limits the increase in (dulcitol) fermenting powers varied with the length of sojourn in a (dulcitol) containing medium. The increased activity as regards fermentation of dulcitol persisted through several generations of agar cultures but eventually tended to die out. It also persisted on stored agar cultures for over a month if that culture be subcultivated and tested. No other modifications either as regards agglutination, fermentation reactions, or cultural characteristics were seen in the agar cultures after passage through dulcitol (or arabinose) containing media other than the increased activity towards the corresponding "sugar." The cultures after passage through dulcitol become "dulcitol active," and after passage through arabinose "arabinose active." The "dulcitol active" cultures did not show any increased activity towards arabinose nor did the "arabinose" active cultures show any increased activity towards dulcitol. Mere passage through peptone water or through other sugars—e.g., mannitol, lactose, or saccharose—did not increase the fermentative activity towards dulcitol or arabinose. It was not found possible to make bacillus typhosus ferment lactose or saccharose. By means of passage through appropriate sugars it was found possible to develop two modifications of a coliform organism, each active toward a new sugar not easily affected by the original strain. The fermentation activity of bacillus typhosus, while one of remarkable constancy in quality, could be increased in quantity and suggested that certain work of classification amongst colon organisms required reconsideration.

Professor S. ARTHUR POWELL of Grant Medical College, Bombay, communicated a paper on the Bentley-Taylor Method of Mounting Mosquitoes. The process was as follows. Prepare (1) a solution of 1 per cent. celloidin in absolute alcohol; and (2) a solution of celloidin in absolute alcohol of the consistence known as "thick" in ordinary histological work. He believed that used for those insects was 5 per cent. It was essential that no ether be employed in the solution as it made the scales transparent. Catch the mosquito, chloroform it, and when dead or narcotised place a drop of solution 1—thin celloidin—on a cover-glass. Place the insect back downwards on the cover-glass. In the majority of cases wings and legs spread themselves out in the orthodox exhibition position. If they did not do so the solution remained fluid sufficiently long enough in Bombay at a temperature of 85° to 90° F., for from three to five minutes, to permit them to be adjusted with a needle. When the thin solution had become "tacky," to use the language of the motorist—i.e., in about eight or ten minutes from the commencement of operations—place a drop of the thick solution, No. 2, over the insect. Invert the cover-glass over a hollowed slide, to which it may be fixed by a ring of balsam. The specimen was then complete, and in that condition both ventral and dorsal surfaces could be examined under the microscope.

OTOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 18th, Mr. ARTHUR H. CHEATLE, the President, being in the chair.

The PRESIDENT showed: 1. A case of Congenital Malformation of the Auricle and Meatus. An X ray photograph had shown the presence of mastoid cells. An exploratory operation had been performed, but no meatus was found. There was no evidence of the tympanic plate. 2. A case of Healed Fracture of the Right Temporal Bone in which the line of fracture in the meatus could be seen. The patient was a man, aged 30 years, with a fracture of the base of the skull, involving the right temporal bone, at the age of 10 years. Middle-ear deafness had resulted. The President also recorded a note of a case of Nerve Deafness in a syphilitic of 30 years' standing. The patient, a man, aged 51 years, had had syphilis at the age of 21. For seven or eight years he had noticed the gradual onset of deafness, with ringing tinnitus in both ears. The Wassermann test was positive.

Dr. H. J. DAVIS showed: 1. A specimen of Temporal Bone from a case of thrombosis of the cavernous sinus; proptosis and suppurative phlebitis of both orbits following right mastoid disease of 20 years' duration; extra-dural abscess; the lateral sinus and jugular vein were unaffected. The patient was a woman aged 36 years. 2. A case of Extra-dural Abscess tracking through the Jugular Foramen into the Neck; sloughing of the middle-third of the internal jugular vein; operation; recovery. The patient was a girl, aged 19 years, whose illness began with sickness and shivering fits. She had been treated as a doubtful case of enteric fever for five weeks before operation. Widal's reaction was negative.

Mr. SYDNEY R. SCOTT recorded two cases: (1) A case of Lateral Sinus Thrombosis (Streptococcal) with Early Pulmonary Metastasis; recovery. (2) A case of Retro-cerebellar Abscess; Necropsy. This was a case of latent mastoid disease in which an extra-dural parasinous abscess had formed and was followed by retro-cerebellar intra-dural abscess. The path of infection along the great horizontal fissure of the cerebellum could be traced.

Dr. DAN MCKENZIE showed a case of Infiltration of both Auricles (? Chronic Lymphangitis), in a woman, aged 32 years. A vaccine had been prepared from the moisture in the depths of the meatus and injected subcutaneously, with the peculiar result that certain fleeting attacks of local cutaneous inflammation had ceased to appear. Lymph-angioplasty had had no very decided effect.

Mr. C. E. WEST showed two patients: (1) A case of Chronic Dermatitis of the Pinna due to Infection by Staphylococcus Aureus, which, under treatment by vaccine, showed signs of improvement. (2) A case of Chronic Infective Labyrinthitis. The patient, a female, aged 23 years, had had right facial paralysis for about a week: total right deafness and loss of thermal excetibility before the radical mastoid operation. The facial nerve was found to be absolutely isolated by granulations which sprouted from the labyrinth.

Dr. W. H. KELSON showed the Brain of a Patient who died from Cerebellar Abscess. Operation for nasal polypi; acute otitis media; radical mastoid operation. Cerebellar abscess opened, followed after 26 days by death. A necropsy was performed. The infection was streptococcal. The brain showed the site of the abscess surrounded by œdema and a small secondary focus of infection on the upper surface of the adjacent cerebellar hemisphere.

Mr. H. J. MARRIAGE showed a large Tuberculous Polyp removed from the Middle-ear of an Infant aged 7 months. A microscopical examination had been made. Radical

mastoid operation was performed. Twelve days after operation an injection of tuberculin was given. Three months later tuberculous dactylitis developed. Six months later tuberculous glands were removed from the neck. The child had grown into a fine sturdy boy.

Mr. G. SECCOMBE HETT showed a case of Malformed Auricle (Congenital) in a child.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Nov. 14th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. CECIL WALL showed two cases of Myasthenia Gravis. In the first case the patient was a coachman, aged 30 years. The condition had lasted for 15 months. The patient dated the commencement of the illness from a nervous shock received whilst driving a pair of horses in a thunderstorm. Subsequently general weakness became noticeable, affecting all parts of the body. In the second case the patient was a female, aged 21 years. The condition started five years ago, commencing with diplopia and drooping of the eyelids, and general weakness followed.

Dr. A. F. VOELCKER showed a case of Myasthenia Gravis. The patient was a brass-worker, aged 14 years, whose illness commenced five months ago, when he noticed that towards the end of the day he was unable to talk clearly.

Mr. H. A. T. FAIRBANK showed a case of Bilateral Congenital Dislocation of the Patella after Operation. The patient was a girl, aged 6 years, who went to the Hospital for Sick Children, Great Ormond-street, in November, 1909, complaining that the knees gave way. Examination showed outward dislocation of the patella on flexion of the knees. The right knee-joint was exposed by raising a skin flap; a fusiform piece of capsule and synovial membrane was excised from the inner side of the joint. A vertical incision was made through the capsule on the outer side of the patella, the capsule was raised to the outer side of this, and the synovial membrane was incised vertically well to the outer side of the capsular incision. Incision of the capsule and synovial membrane in different places allowed the patella to be drawn inwards without leaving much of a gap on its outer side. The incisions on each side of the patella were then carried down beside the ligamentum patellæ and through the periosteum on each side of, and to a lower level than, the tubercle of the tibia. The insertion of the ligamentum with the periosteum below were then raised and swung inwards and fixed in their position with a screw. The periosteum was left undivided below, so that the insertion of the quadriceps into the tibia was never really divided. The edges of the gap on the inner side of the joint were brought together with catgut; the skin flap was brought across the front of the joint and the wound was closed. The left knee-joint was treated in an almost similar manner. Both patellæ were now in their normal positions and apparently were not inclined to relapse. The child walked stiffly, and flexion of the knees was limited on both sides owing to deficient length of the quadriceps muscles, which had never been developed to the normal length.

Mr. P. MAYNARD HEATH showed the case of a boy with a Supracondylar Process of the Humerus. The patient's mother noticed a lump on the inner side of the right arm a month ago. It had given rise to no symptoms. The X ray plate showed a typical supracondylar process of the humerus.

Mr. DUNCAN C. L. FITZWILLIAMS showed two cases of Dislocation of the Inner End of the Clavicle.

Mr. W. C. G. ASHDOWNE showed a case of Multiple Cartilaginous Exostoses. The patient was a male, aged 21 years, with exostoses of the long bones of the extremities. One growth was removed in 1907 from the inner surface of the left tibia as it was coming through the skin, and at the same time both bones of the leg were divided to correct genu varum.

Mr. A. E. BARKER showed five cases. The first was one of Recovery after Acute Pancreatitis.[1] The second was a case of Removal of Carcinoma of the Splenic Flexure done six years ago. The patient was still apparently free from recurrence. Only a little mucus escaped occasionally from the stump of the ileum. The third was a case of Removal of Carcinoma of the Transverse Colon involving the Umbilicus and Abdominal Wall. The fourth was a case of Removal of Transverse Colon adherent to Tumour in the Umbilicus. The patient, aged 35 years, was admitted for a discharging lump of the size of a large egg in the umbilicus. This was excised with the transverse colon, to which it was adherent. The lump was apparently one of those rare tumours of the umbilicus derived from fœtal remnants left in the umbilicus somewhat of the nature of a dermoid. The patient made an excellent recovery. The fifth case was one of Appendical Abscess in a female, aged 38 years, who was operated on in Brighton two and a half years ago for appendical abscess. This was followed by fæcal fistula and great emaciation. For this she was sent to Mr. Barker two years ago. There was then discharge of fæces in the right iliac region, and underneath this a large hard mass. On opening the abdomen extensive tuberculous infection in and around the cæcum was found. The ileum two feet above the valve was first planted into the transverse colon end to side. Then the hepatic flexure of the colon was cut across and closed above the junction. The ascending colon, cæcum, and last two feet of ileum were then completely removed.

Dr. HERBERT S. FRENCH showed two cases of Locomotor Ataxy with absence of knee-jerk on the right side and well-marked knee-jerk upon the left.

Dr. J. W. CARR showed a case of Choreiform Movements in a man, aged 30 years, who had involuntary jerky movements of all the muscles of the body, most marked when attention was directed to them. They diminished when he kept perfectly quiet, and ceased during sleep. Voluntary muscular movements tended to diminish the involuntary ones and the man could get about fairly well, but there was considerable general muscular weakness. There was no evidence of organic disease. The treatment adopted had been rest, isolation, spinal douches, faradism to the back, and nerve sedatives, but there had been very little improvement.

Mr. V. WARREN LOW showed a case of Benign Growth in the Tibia of a boy, and a case of Marked Congenital Syphilis of Bone in a man 38 years of age.

Dr. CHARLES W. CHAPMAN showed a case of Generalised Atheroma without apparent valvular disease, whose symptoms of palpitation and forcible action of the heart followed by a duration of complete stoppage, also of substernal pain at times severe in character, cleared up under iodide of sodium.

[1] THE LANCET, Oct. 29th, 1910, p. 1264.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Yellow Fever.

A MEETING of this society was held on Nov. 18th, Professor RONALD ROSS being in the chair.

Sir RUBERT W. BOYCE read a paper on Yellow Fever in West Africa. He said that his paper was the result of investigations made during June, July, and August, 1910, at the request of the Colonial Office. For the purposes of this investigation he visited Southern Nigeria, the Gold Coast and Sierra Leone, and the Sierra Leone Protectorate. The present inquiry formed the fourth upon which he had been engaged. The first question he put to himself was: What was the prevalence of the stegomyia calopus in West Africa? He soon satisfied himself that it was by far the most common mosquito of a very large number of towns. In yellow fever, as in the case of the sister disease, malaria, the continuous or endemic source of infection was the comparatively dense native population of the West Coast. The historical record of outbreaks and sporadic cases, mistaken diagnosis, and the absence of any destruction of infected stegomyia in the past was evidence in favour of the disease being endemic on the coast and of its having been repeatedly mistaken for other diseases or entirely overlooked. Reluctance to diagnose yellow fever had been universal and existed at the present day. There appeared, as it were, to have been a universal conspiracy to deny the presence of yellow fever. Some said that the fever was of no account, only attacking the new arrival; others wished to have nothing said, as quarantine authorities were insisting on rigid regulations; others thought that as the name

caused such a panic amongst the public, the better and more business-like policy was to say nothing about the disease, or to deny its existence or return it as some other disease, or make light of it. There was no doubt that the young medical officer had experienced great difficulty in deciding what is and what is not yellow fever. Until the dreaded black vomit appeared physicians had hesitated to diagnose it, and in the meantime the harm had been done and the disease had spread. Carroll had stated that experiments showed that genuine yellow fever might be so mild in character that no man, no matter how extensive his experience might have been, would dare to diagnose it as such, unless he knew the disease to be prevailing at the time. Yellow fever had masqueraded under many euphonisms as "inflammatory fever," bilious remittent fever, and intermittent fever. Continuing, Sir Rubert Boyce said that it seemed strange that there should be obstacles in the way of the diagnosis and notification of yellow fever; but such was the case. In all the outbreaks which he had had to investigate, he had encountered them, and writers upon yellow fever had, time and time again, drawn attention to that point. Sir Rubert Boyce concluded by stating that yellow fever was endemic and common in West Africa, and occurred there in all its various forms. There was but one remedy, and that was stegomyia destruction; and there was but one result to expect—namely, a most marked increase in the health and prosperity of West Africa.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Marriage, Insanity, and Degeneration.

THE quarterly meeting of this association was held at the rooms of the Medical Society of London, Chandos-street, W., on Nov. 15th, Dr. JOHN MACPHERSON, the President, being in the chair.

A resolution of congratulation to the President on his restoration to health after a severe illness was cordially approved.

Dr. G. H. SAVAGE read a contribution on Insanity and Marriage, in which he said that the subject of marriage in relation to insanity was at present beyond practical legislation in this country, but it was of immense importance for the social stability and for individual welfare. Though physicians could not legislate, they had to advise, and that advice was sometimes taken. A dogmatic statement that the insane should never be allowed to marry was unscientific and unpractical, for it assumed that all insanity was alike and was to be treated as of equal value. Adolescent cases with melancholic symptoms or maniacal excitement recovered completely. He had also encountered cases of women who had had attacks of insanity before the menopause who had married when that period had passed and remained well, but few would recommend such unions. Unions after acute delusional insanity, of probable toxic origin, had also turned out well, but he would hesitate to advise such. The question of family neurosis would influence the advice given, while dread of recurrence might act in some subjects as an auto-suggestion. Marriage should be hindered or prevented in cases with a history of recurrences, and in youths showing alternating periods of depression and buoyancy, and the suppression of such material facts should be a ground of nullity. It was impossible to prevent the marriage of all who were related to the insane, and it would not be good as he had seen successful families reared by neurotics. He would never allow marriage where there were fully organised delusions or hallucinations, nor in epilepsy accompanied by mental symptoms. Moral perversions should also be a bar, and marriage with the idea of reformation should be discouraged. Marriage was no relief for neurasthenia or hypochondriasis, and after sexual disorder it was dangerous. Dr. Savage concluded his paper by propounding the following questions: Should anyone who has been certified as of unsound mind be allowed to marry? If so, which cases, or which forms of insanity, may be considered as not barring healthy unions and healthy offspring? Should not the recurrence of any form of insanity be a bar? Should evidence of syphilitic affection of the central nervous system bar marriage? Should marriage ever be recommended in cases of mental disorder? Should insanity be a plea for divorce?

Dr. C. T. EWART, in a paper entitled "Eugenics and Degeneracy," said that his object was to consider whether it was advisable to discourage parenthood of the unfit, and to encourage large families by the fit, with a view to national efficiency. Nations which became luxurious and idle decayed. In the elementary schools of the country 35,000 children were mentally defective. 2521 women mentally defective added 1000 illegitimate children to the population yearly. He advocated a higher estimate of woman, whose strength should be husbanded for the future welfare of the race. The giving birth to a new citizen involved a duty to the community in respect of his health, mental and physical, and a claim by the parents on the State that the State should make the conditions of life favourable to that child's efficient growth. There was plenty of good stock in this kingdom, and its reproduction should be encouraged, while checking the continuance of the evil strains. Public opinion looked to the medical profession for guidance towards the welfare of the race.

Mr. MONTAGUE CRACKENTHORPE, K.C., expressed himself dissatisfied at the meagre and often misleading published summaries of evidence tendered to the Divorce Commission. What students of eugenics were in search of was information as to what extent insanity was heritable. Recurrent insanity was much more dangerous to society than permanent mental breakdown, because subjects of the former were let out from control, and thus were able to reproduce, and it seemed a truism that the degenerates were more prolific than the sound. He thought the time had come when marriage should not be permitted in the absence of inquiry as to the history of the members of the families of the contracting parties. He hoped there would be given to the world a pronouncement as to what was and what was not transmissible disease. The aim of those interested in the matter was the elimination of the unfit and the propagation of the fit, with the consequent raising of the level of humanity.

Dr. T. B. HYSLOP said the general public was becoming alive to the fact that there were conditions which brought about degeneracy, and that those must be dealt with first by education, and, if that did not suffice, by legislation. He believed the present Divorce Commission would result in a reform of the conditions under which marriages were entered into. Two classes of people came to the physician for advice as to marriage. The first were afraid the advice would be contrary to their wishes to get married, and so took no notice of it. Others came as a sort of forlorn hope that the physician would forbid the banns, raking up all sorts of eccentricities to support their wish. He believed that in the future medical fitness would be inquired for before the celebration of a marriage.

Dr. H. B. DONKIN believed the time was not yet when anyone could say certain qualities were, and certain qualities were not, inherited, though gross bodily defect could be more definitely pronounced upon. Only in regard to the feeble-minded, in mental matters, could one be dogmatic.

Dr. C. A. MERCIER contended that the profession did not yet know sufficient to be able to say what qualities were hereditable and what were not. Certainly the time had not arrived when the legislature could be advised what would tend to the most successful marriages. Those who spoke of restriction of procreation did not realise that such restriction had always prevailed, even among savage races.

Miss DENDY spoke of the difficulty of getting reliable family histories in the case of the applicants for admission to her home. Much had been said about the danger of weak-minded girls being on the streets, but too little attention had been paid to the question of the same class of boys. In her institution the inmates were treated as children, and they were quite happy in their surroundings.

Dr. FLETCHER BEACH reminded the members that progress could only take place by increasing the fit and decreasing the unfit, and the latter should be permanently kept in institutions. He had long contended that cases of moral imbecility should be kept in institutions where they could be profitably employed and cease to be defects at large. Feeble-minded girls continually became mothers, and steps should be taken to prevent that. We were travelling towards a fall, and the only way to arrest that fall was for the State to interfere.

Mr. H. F. HAYES NEWINGTON agreed with Dr. Mercier that enough was not yet known by the medical profession on the

subject to give any legislative lead. Moreover, he did not think the Divorce Commission had the impression from alienists which the collective membership of the association would give. In such a matter humanity was subject to tremendous laws, far above human laws, and to interfere without adequate knowledge would be wrong.

Dr. JOHN CARSWELL said there was a mental defect which showed itself only in very limited degree in infancy and childhood. The child was equal to passing the ordinary examinations at school up to the third or fourth standard, but later could not adjust himself or herself to the simplest environment. Such people became aggressive, and not only asocial, but anti-social. There was a form of feeble-mindedness which became manifest after puberty, and was not to be confounded with dementia præcox. The remedies suggested in the present discussion did not appeal to him, and he endorsed the remarks made by Dr. Mercier. Nothing had been said as to the influence of alcohol in producing unfitness, and that was significant. Evidence was not clear enough to enable one to be dogmatic on the question of inheritance.

Mr. J. F. BRISCOE objected to the use of the term "divorce" when speaking of insanity or other disability as a cause of annulment of marriage. He suggested that a committee of the association should make a collective investigation of facts bearing upon the subject.

Dr. J. BEVERIDGE SPENCE expressed his agreement with the remarks of Dr. Mercier and Mr. Newington as to the insufficiency of the data available to enable the profession to give a guide on the matter. He thought a beginning should be made to isolate defective children to prevent them propagating their species.

Dr. M. EDEN PAUL said he thought it was the duty of the medical profession to use the influence it had in the direction of a sane extension of eugenic conceptions. It would not be right for physicians to fold their hands and say they had no knowledge. On the question of epilepsy and feeble-minded, knowledge was sufficiently definite to be most useful for the general good.

Dr. T. D. GREENLEES deprecated the assumption of ignorance on the part of the association on such an important matter, and reminded members that it was to the association the legislature would look if it wanted information to guide it. He thought the matter could be referred to a Parliamentary committee of the association for collective investigation.

The PRESIDENT agreed as to the paucity of real definite knowledge on the transmissibility of qualities, and declared that no really fundamental advance in biology had been made since the days of Darwin, if one excepted the branch of embryology. The time has not yet come for giving the definite pronouncement which Dr. Ewart desired.

Dr. EWART, in summarising the debate, restated his position.

THE UNITED SERVICES MEDICAL SOCIETY.

Malingering.—Guinea Worm.

A MEETING of this society was held on Nov. 9th, Colonel Sir DAVID BRUCE being in the chair.

Major C. E. POLLOCK R.A.M.C., read a paper on Malingering. After discussing the various motives for malingering—viz., to avoid an unpleasant duty or the consequences of misconduct, home-sickness, desire to get out of the service, and hope of obtaining compensation for supposed injuries—he went on to describe the more usual methods of "malingerers" in the British Service; of these feigned mental disease was the most important. It was a curious fact that as many as 80 per cent. of those invalided for insanity from India recovered on the voyage home. Major Pollock advocated the establishment of a central institution in India for the careful observation of cases of mental disability. It was important that men should not be allowed to evade their obligations by shamming madness, but at the same time it was very necessary to be extremely cautious about coming to the conclusion that a mental case was one of malingering; for if one discharged the man and he went and did something really foolish, such as discharging a rifle in a barrack-room, one was put in an awkward position, since it would be very difficult to decide whether the foolish act was that of a madman or only the supreme effort of a malingerer to obtain his end. The speaker then described various other forms of malingering—assumed fits, pretended defects of hearing, vision, speech, voluntary starvation, spurious pyrexia, hæmoptysis, &c.; he discussed the methods by which the various deceptions could be detected. Lastly, he dealt with the numerous methods of mutilation which were attempted in countries where conscription was in vogue by people who wished to evade their military service. The retired Russian *feldsher* is a past-master in the arts necessary to a "conscript's friend"; he included in his practice the production of artificial hernia, spurious tumours by the injection of paraffin, hammer-toe by fixing the toes in a plaster bandage for some months, and numerous other devices of that kind to deceive the examining medical officer, and to secure exemption from military duty.—Brigade-Surgeon J. F. BEATTIE said that when he was serving he saw no malingering; he believed that when malingering did occur to any extent it was evidence that the men were not being properly managed.—Surgeon-General W. L. GUBBINS endorsed Major Pollock's opinion that one should be specially careful in coming to the conclusion that a man was malingering; he cited instances in support of this. In the case of mental disease, it had to be remembered that soldiers were armed, and it was better to make a mistake and to allow a malingerer to pass than to have a tragedy. The proposal to establish one place for observation of mental cases in India was not practicable on account of the distances to travel; there should be four or five. He thought that at home all mental cases should be transferred to "D" block at Netley for observation.—Major W. S. HARRISON R.A.M.C., said that with regard to spurious palpitation, it was known that this had been produced by chewing cordite, which caused similar symptoms to those caused by the ingestion of nitrites. He referred to the case of a Royal Army Medical Corps recruit who came under his care complaining of pain in the loin radiating down into the testicle and who stated that his urine was bloody after the attack. When he was admitted there was no blood in the urine, but on the following day there was a copious deposit of what appeared to be pus. Microscopic examination, however, showed that the supposed pus consisted of starch granules, and it had evidently been simulated by the addition of dusting powder to the urine.

Major S. L. CUMMINS, R.A.M.C., read a paper on Guinea-worm, which parasite, he stated, had caused great loss of efficiency to garrisons of native troops serving in endemic areas, and pointed out that, if it were ever necessary for British troops to serve in tropical Africa, the conditions of water-supply in many places would make this disease a serious menace to health. The strategical importance of the disease, however, was diminished by the fact that it took nearly a year to develop, so that it could not complicate military operations lasting less than 12 months. Referring to the position of emergence of the female in the human host, the preference of the parasite for the lower extremity—the position most suitable for the discharge of the embryo into water—was shown by the tabulated results. In one series all the worms emerged in the lower extremity; in another and larger series this occurred in over 80 per cent. of the cases. The tendency to abscess-formation in cases where the embryos were set free in the tissues by rupture of the worm was mentioned. This danger was shown to be common in cases treated by injections of perchloride of mercury solution also, but was attributed in the latter case to stimulation of the fluid bringing about a discharge of embryos in the tissues, just as happens when fluid is applied to the projecting worm. The danger of these abscesses, when the worm was situated in the vicinity of joints, was illustrated by quoting a case where the knee-joint was infected in this manner, necessitating opening and drainage of the joint. Major Cummins expressed the opinion that, where the worm was in a safe situation, careful traction by winding on a quill or match was the most expeditious method of treatment, but advocated the slower and safer method by daily douching with cold water when the worm was in the vicinity of a joint. The prophylaxis, though simple in theory, and consisting in clarifying infected water before use on the one hand and protecting water from infection by cases on the other, was shown to be difficult in practice owing to the conditions prevailing in endemic areas. A hope was expressed that further study of the habits and history of the cyclops, on the lines initiated by Graham, might lead to a scientific prophylaxis aimed at getting rid of the intermediate host.—Lieutenant-Colonel Sir W. B. LEISHMAN, R.A.M.C., inquired

as to the habits of Egyptian soldiers in the matter of wading in water. He was very sceptical about the intelligence of filariæ leading them to go to parts where transmission to other hosts was facilitated. He asked if Major Cummins had had any experience of the treatment by injecting perchloride of mercury directly into the prolapsed uterine opening of the worm.—Major CUMMINS replied that at home in Egypt the men lived a great deal in the water, but in the Soudan they wore boots and were not so constantly in the water, but the Soudanese, who were the main source of infection, were constantly paddling in the water up to their knees.

EDINBURGH OBSTETRICAL SOCIETY.

Presidential Address.—Election of Officers.

A MEETING of this society was held on Nov. 9th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Dr. HAULTAIN, in his Presidential address, referred to the important part Edinburgh had played in the development of gynæcology, mentioning the names of Sir James Y. Simpson, Lister, Keith, and Tait. He traced the development of ovariotomy, which might be looked upon as the *doyen* of abdominal surgery. The pedicle was first secured extra-abdominally by clamps, then it was clamped, seared, and dropped into the abdominal cavity; later to this was added by Angus Macdonald the ligation of the vessels by silver wire and suture. The cautery was then discarded, and the pedicle secured by silk, catgut, or linen tied *en bloc* by a variety of knots, such as Staffordshire and Bantock, and then dropped into the peritoneal cavity. From this we had advanced to ligation in parts and careful inversion of the raw stump, with subsequent covering by peritoneum. The abdominal wound had been closed by pins, silver wire, silk and silkworm gut *en masse;* now the preponderance of opinion was more sentimental, and tended towards the use of catgut in layers, with a final subcutaneous continuous suture. The after-treatment had undergone much change; at first the patient was kept rigidly on her back, and for the first 48 hours not a drop of water was allowed to be swallowed, while the bowels were locked for eight days. Now free movement was permitted to the patients, fluids were given freely whenever they could be retained, and the bowels were freely moved on the second or third day. During the "eighties" and early "nineties" drainage by the abdomen or vagina was advised in even simple cases; now it was practically universally discarded. Following upon the pursuit of ovariotomy other conditions were recognised and treated by removal when required, diseases of the appendages, extra-uterine gestation, and uterine fibromyomata. Compared with the advances in gynæcology, midwifery had not shown the same degree of development. Since the late "seventies" the management of pregnancy, labour, and the puerperium had shown advancement. Antiseptics had made a great revolution in their methods; the addition of axis-traction rods to the forceps, the use of hot water in post-partum hæmorrhage, and the application of surgical procedure by abdominal and other methods were all important developments. One would naturally expect some reflection of these improvements in the Registrar-General's tables, but when these were consulted one was staggered at the figures. The mortality from puerperal causes in Scotland was as high as it was 50 years ago—viz., about 5 per 1000, or 1 in 200. Before 1878 the puerperal death-rate in Scotland was 4·8 per 1000, and 4·9 since 1878; while from puerperal fever it was 1·7 per 1000 before 1878, and 2·0 since. Those of Edinburgh were very similar, being from all causes 5·6 per 1000 before 1878, and 4·9 since; from puerperal fever 2·1 before 1878, and 1·9 since. It might be suggested that registration was now more strict, and the grouping of diseases more accurate. So far as puerperal fever was concerned, the death-rate in England and Wales was very similar—viz., in 1855 1·6 per 1000, in 1908 1·4, and it must be remembered that the great bulk of the cases were attended by midwives. The statistics from other countries showed a variable result, but in every instance cited there was a marked diminution, till in Sweden, Holland and Italy it was under 1 per 1000. Facts such as these seemed to prove that in the United Kingdom the fever death-rate in spite of antiseptics still remained the same. The effects of antiseptics had undoubtedly been proved to be of the greatest benefit in hospital treatment of maternity cases, but in private practice so far as statistics showed there was little evidence of their being of value. The results fell far below the legitimate expectations. There was no reasonable doubt that labours in general in the light of modern knowledge of infection were now more carefully and cleanly treated than formerly; here it was impossible that direct heterogeneous infection could be so common. Further, the cure of many infected cases by antiseptics must be accepted. In the face of this they could only account for the maintenance of the death-rate at the same percentage by an increase of germs in their surroundings, the result of centralisation in cities and overcrowding. This was only in keeping with the marked increase of appendicitis, septic pneumonias, and similar affections. By antiseptics it seemed they had been able to keep the death-rate where it was; without them the results would have been worse. This was aptly illustrated by the statistics from puerperal septicæmia in England and Wales. Till 1900 there was an increasing death-rate from sepsis; since then it had decidedly dropped; this might fairly be attributed to the adoption of the Midwives Act. In 1902 the deaths from puerperal sepsis were 118 per million women; in 1907 they fell to 81. This meant the saving of hundreds of maternal lives. The President then referred to the enormous increase of deaths from eclampsia in Scotland. In the years 1906 to 1909 the incidence of cases and mortality were much the same in the Rotunda and Queen Charlotte's Hospitals—viz., 0·5 per cent. of eclamptic cases, of which 14 per cent. were fatal. In St. Mary's Hospital, Manchester, 0·24 per cent. were eclampsia cases and the mortality of these was 63·6 per cent., while in Edinburgh there were 3 per cent., or six times greater than in Dublin or London, and the death-rate in these cases was 35 per cent., or two and a half times more fatal. The methods of treatment were similar to those of other institutions. It was feasible that the marked increase in Scotland was due to the great difference in the diet of the populace, who a generation ago subsisted more on a cereal diet instead of the highly nitrogenous diet they now adopted, and the colder climate had apparently some effect on the development of eclampsia. The President looked into the future and expected the development of a new specialty as represented by the "abdominal surgeon." It was, on the one hand, essential that the gynæcologist must be a thoroughly trained surgeon, while on the other the surgeon must be a thoroughly trained obstetrician to deal with the diagnosis and development of conditions of pelvic origin. The expert gynæcologist must be an expert obstetrician. In conclusion, he referred to the practical obstetrical training of students.

The following office-bearers were elected for the ensuing session:—President: Dr. F. W. N. Haultain. Vice-Presidents: Dr. J. Lamond Lackie and Dr. N. T. Brewis. Treasurer: Dr. G. F. Barbour Simpson. Secretaries: Dr. Angus Macdonald and Dr. B. P. Watson. Librarian: Dr. Lamond Lackie. Editor of Transactions: Dr. H. Oliphant Nicholson. Members of Council: Professor W. Stephenson (Aberdeen), Dr. Frederick Porter, Dr. F. D. Simpson, Dr. J. Haig Ferguson, Dr. W. Craig, Dr. E. H. Lawrence Oliphant (Glasgow), Professor J. A. C. Kynoch (Dundee), and Dr. Kenmure D. Melville.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 16th, Mr. W. Morley Willis, the President, being in the chair.—Dr. P. Boobbyer, medical officer of health of Nottingham, opened a discussion on Infantile Diarrhœa, and said that not only was epidemic diarrhœa very largely the cause of the high infant mortality, but an excess of epidemic diarrhœa was followed by an excess of the infant mortality rate. It was a disease chiefly of the urban districts, and was greatly exaggerated by overcrowding, lack of ventilation and sunlight, defective scavenging, and a high temperature accompanied by drought. In prophylactic treatment the conditions existing in rural districts should be followed in cottage homes. The figures of Leicester were most encouraging. In 1873 the diarrhœa infant mortality rate was 223 per 100,000. At that time the local conditions and scavenging were similar to those of Nottingham. Leicester had, however, now converted its system of dry scavenging to the water system with the result that the death-rate from epidemic diarrhœa had fallen to

31 per 100,000; that of Nottingham, where the tub system still existed, varied from 69 to 97 per 100,000.—Dr. W. Tibbles, while agreeing as to the infective nature of diarrhœa, laid great stress upon the part played by improper feeding in its causation. Breast-fed children seldom suffered from diarrhœa; it occurred chiefly in bottle-fed children or those recently weaned. He classified the causes as (*a*) *autogenetic*—gastro-enteric catarrh, intestinal fermentation, toxæmia; and (*b*) *heterogenetic*—improper feeding, mechanical irritation, nervous influences, bacteria. Excess of casein caused diarrhœa by mechanical irritation or putrefactive decomposition; excess of carbohydrates by the nature of the sugar—e.g., maltose or malted foods; or by mechanical irritation—e.g., bread, cereal foods, fruit, vegetables. Excess of fat, especially from cow's milk or centrifugal cream, might cause diarrhœa. Fat was exceedingly important, but many infants were unable to digest food containing more than 1 per cent. fat from cow's milk or cream. Summer diarrhœa was not due to heat alone but to bacteria. In the autogenetic form the normal bacteria of the intestines became pathogenic and caused a severe gastro-enteric catarrh with toxæmia. The heterogenetic form was due to bacteria, usually introduced with the food, the toxins of which profoundly affected the heart and nerve centres. There were several clinical types which, however, depended less on the kind of bacteria than other conditions. In the treatment vomiting was to be allayed by lime-water, milk of magnesia, washing out the stomach, and rest from food. Astringents were of little value in the acute phase; the bacteria should be eliminated by purgatives, colon lavage, antiseptic drugs, and abstinence from ordinary foods. After the cessation of vomiting, moderation of purging, and reduction of temperature, bismuth, aromatic powder of chalk, or tannigen might be of service. The depression must be fought by stimulants; if they were vomited, strychnine and ether or normal saline solution should be injected subcutaneously. Dietetic treatment was prophylactic and remedial. Breast-feeding should be encouraged; weaning of children during the summer months should be avoided. Bottle-fed children must have pure milk made into mixtures of proper composition and suited to their age. Improper foods, especially excess of casein and malted foods, must be avoided. During the diarrhœa children should be kept from the breast until the cessation of vomiting, when they might be allowed to suck for two or three minutes at a time and be fed every two hours with albumin-water or whey. Bottle-fed children should only be given water or barley-water until vomiting ceased; when this was retained they should be cautiously fed with egg albumin and water, whey, white wine whey, buttermilk, chicken or veal broth, one drachm every 15 minutes, or a meat juice. As the acute stage passed off dextrinised foods might be given with barley-water or whey. Egg mixtures were now valuable; those foods in which milk casein had been modified, such as whey, whey and cream, buttermilk, peptonised milk, and koumiss, were applicable until convalescence was established; the return to normal food must be as gradual as the return to health.—Dr. C. H. Cattle said that summer diarrhœa was a zymotic infective disease, but was not actually due to a single specific bacillus. The treatment might be summed up in elimination of the toxins—e.g., washing out of the stomach, lavage of the bowel, and purgatives. It was important to eliminate the milk from the diet, because the curd of the milk was irritating to the bowel. He recommended water in large amount and saline injections subcutaneously.—Dr. A. C. Reid discussed the serum treatment of the disease and said that Morgan had isolated a definite bacillus called "Morgan's bacillus"; and from injection of this into horses he had obtained an antitoxic serum. Dr. Reid had employed the serum in 13 severe cases. He injected 9 to 10 c.c. of the serum into the scapular region and had eight recoveries. In the five fatal cases there was definite improvement at first in three, the diarrhœa diminishing to a very large extent, but after three to five days these three cases suddenly collapsed. The two remaining fatal cases showed no reaction whatever. All these 13 cases were of a very severe type. The results of the treatment were encouraging, and he would certainly extend his trial of the method.—Mr. A. Fulton, after deploring the unsuitability of the name of epidemic diarrhœa, said that hand-feeding was a constant factor in its causation. For that reason he discouraged weaning at the beginning of the summer months, especially as the disease was almost always confined to children under 12 months of age.—Mr. R. M. Rendall said that the collapse should be treated by a hot mustard bath with strychnine and brandy. He gave tepid water *ad lib.* by the mouth and ordered castor oil with small doses of opium.—Dr. J. A. Waring thought the commonest cause was a chemical toxin produced in the stomach and that this stimulated a vomiting centre in the brain. He regarded flies as carriers in this disease and had noticed that epidemics coincided with huge swarms of flies.—Dr. F. H. Jacob laid great stress on giving large quantities of water per rectum.—Dr. W. T. Rowe noticed that children under three months were not so susceptible to the disease; this was due to the fact that they were almost all breast-fed up to that time. He regarded breast-feeding as a better prophylactic treatment even then improved scavenging. He thought it a mistake to try to stop the diarrhœa too soon as that prevented the elimination of the toxins. He recommended 1-50th grain of morphia subcutaneously.—Dr. J. Mackenzie (East Kirkby) gave figures of three neighbouring villages showing the effect of the subsoil on the disease.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Sheffield on Nov. 18th, Dr. W. K. Walls (Manchester), the President, being in the chair.—Mr. R. Favell (Sheffield) reported a case of Hysterectomy for Complete Rupture of the Uterus. The patient was a secundipara aged 24 years. The first labour was a natural one. On the present occasion, after being in labour 16 hours, her medical attendant applied forceps, when the os was nearly fully dilated, and with considerable difficulty extracted a living child. As the placenta could not be expressed he introduced his hand and found the placenta amongst the intestines. There was no marked shock nor hæmorrhage at the time. On admission to hospital an hour and a half later she was very collapsed and pale, the pulse being 140 and the temperature 98° F. She did not complain of any pain. The abdomen was somewhat distended but not tender. The fundus uteri was in the middle line. There was only slight vaginal bleeding. Vaginal examination, under anæsthesia, revealed an extensive rent in the posterior wall of the supravaginal cervix. Through this several large blood clots were removed from the pouch of Douglas. The abdomen was at once opened. There was a large quantity of free blood in the cavity. The rupture was seen to involve the posterior two-thirds of the supravaginal cervix. The main vessels were clamped and the broad ligaments and utero-vesical fold of peritoneum divided. The uterus was removed by cutting through the remaining third of the supravaginal cervix. The clamps were replaced by ligatures and the peritoneal flaps completely sutured. The patient made a good recovery.—Dr. J. B. Hellier (Leeds) reported a case in which a Hair-pin embedded in the Uterine Wall was revealed by skiagraphy. The patient stated that she had sat down on a chair into the seat of which a child had fixed a hair-pin with the sharp points upwards. She found that the hair-pin had passed into the vagina and that it held her fast so that she could not rise until she had broken part of it off. A little bleeding followed but no pain. Digital examination failed to find the pin. A skiagram showed one limb of it, lying above the pubes in a more or less vertical direction. The lowest point of the shadow was ¾ inch and the highest 2 inches above the pubes. The patient, who was very thin, was then thoroughly examined under anæsthesia. The uterus was found to be retroverted. Recto-abdominal and vagino-abdominal bimanual examination, passing the uterine sound, and examining the bladder by sound and cystoscope failed to discover the pin. Finally, the anterior fornix was opened and the bladder separated from the cervix. The end of the wire was then found, projecting from the anterior wall of the uterus just above the anterior lip of the cervix. To draw it out required considerable force, in order to straighten out the bend. It must have been entirely embedded in the uterine wall. It was found to measure 2·4 inches. To demonstrate the result of skiagraphing the pelvis with a body of known dimensions in a known position, a second skiagram was made with the patient lying horizontally upon her back as before, after a piece of stout silver wire (3·18 inches in length), with a ring at one end, had been inserted into the

retroverted uterus. The ring lay just outside the os externum. The skiagram showed a shadow ½ inch longer than the wire. The ring lay behind the middle of the symphysis and the wire reached to a point 2·5 inches above the pubes. It must be remembered that the sacral promontory lies 3·75 inches above the pubes, and that in proportion as a foreign body approaches that it will cast a shadow higher than the pubes. A third skiagram was made after introducing into the same patient a Hodge's pessary, made of block tin and measuring 3¼ by 2⅛ inches. The shadow of the upper bar of the Hodge was 1½ inches above the pubes.—Dr. A. W. W. Lea (Manchester) read a paper on the Transverse Supra-symphysary Incision as a method of abdominal section. After relating the history and describing the technique of the method, he pointed out the following advantages which are claimed for it: (1) almost invisible scar; (2 absence of cicatricial contraction or keloid and only a slight tendency to stretching of the cicatrix; (3) hernia practically impossible; (4) the intestines are hardly seen and may be undisturbed during the operation. During the past two and a half years he had used the incision in 65 instances, restricted to cases of relatively small tumours, to inflammatory conditions of the appendages, to operations for ventrofixation of the uterus, and resection of the ovaries and tubes, combined or not with removal of the vermiform appendix. Only one case ended fatally, and that could in no way be attributed to the mode of incision. In all except two the wound healed by primary union. In the two secondary infection occurred along the suture tracks. It speedily resolved. Many of the cases had been seen at varying intervals since. The scar was usually marked only by a thin white line. No case of hernia had occurred nor had any tenderness of the scar been complained of. The following conclusions were presented: 1. The incision may be adopted with advantage in all cases of operation for displacement of the uterus, for inflammatory diseases of the appendages, in the absence of evidence of suppuration, for the smaller ovarian tumours and myomata, for conservative procedures on the appendages, and for tubal gestation. 2. If the patient is placed in the elevated pelvic position excellent access is afforded to the pelvic organs with little disturbance of the intestines. 3. The operation is not suitable if drainage by the abdomen is likely to be needed, but as vaginal drainage is usually employed this is not a valid objection to the operation. Dr. Lea had had no experience of the incision in cases of cancer of the uterus or in large tumours. There was no doubt, however, that by a wide incision sufficient space might be afforded for the necessary operations to be carried out in a satisfactory manner, and experience had conclusively shown that a wide division of the fascia was not attended by any danger of necrosis.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 11th, Dr. A. Christy Wilson, the President, being in the chair.—Dr. J. Stewart read a paper on Some Recent Cases of Cerebral Surgery in which he had operated. In one case there was dislocation of the parietal bone with fracture of the anterior fossa at the base of the skull. The symptoms closely simulated a quite different surgical lesion of the brain. Trephining was performed, with reduction of the dislocation, and recovery ensued. In another case of slight and obscure injury to the brain late hemiplegia supervened. Decompressing trephining was done, with recovery. A third case was that of chronic abscess of the temporo-sphenoidal lobe, symptoms of which suggested tumour. In a fourth case there was an hour-glass subdural and temporo-sphenoidal abscess.—Dr. T. Churton showed a Brain with Hæmorrhage into the Pons and Fourth Ventricle. A man, aged 46 years, became suddenly comatose on Nov. 5th. On admission to hospital half an hour later (5 P.M.) he was convulsed. At 7.30 P.M. he was breathing in short gasps at irregular intervals; the face was dusky; the pulse was full, regular, 80; and the temperature was only 96·5° F. There was no plantar reflex; patellar reflexes were very brisk and extensive, R > L; pupils not contracted; no light-reflex. The eyes were parallel or very slightly divergent. Diagnosis: hæmorrhage into the fourth ventricle. Death occurrred at 10 P.M.; there was no rise of temperature. A diffused bilateral hæmorrhage, apparently originating on the right side, infiltrated the pons. Through a rent in the floor of the fourth ventricle blood had escaped into its cavity. The hæmorrhage did not extend into the substance of the crura. Each lateral ventricle contained one or two ounces of clear fluid.—Dr. C. Oldfield showed the following specimens: 1. Tuberculous Pyosalpinx (one-sided) found attached to the omentum in umbilical hernia. The patient, who was lactating, had regular and profuse menstruation since her confinement nine months previously; the uterus was bulky (4½ inches), but not otherwise abnormal. 2. Hæmatosalpinx (one-sided), due to strangulation of uterine and ovarian vessels from peculiar method of enlargement of hydrosalpinx. The cause of the tubal disease was probably the appendix, which was diseased and attached to the sealed fimbriated extremity of the tube. 3. Stone from the vesical portion of the ureter, of the size of a filbert, which was removed transvesically by vaginal cystotomy.—Dr. E. F. Trevelyan showed a girl, aged 3 years, with Partial Paralysis of the Right Shoulder Muscles, including the serratus magnus, of some four months' duration. A similar paralysis, but not so marked, had recently developed on the other side. Between the onsets of the paralysis in the two arms a slight but definite prominence had been noticed in the lower cervical and upper dorsal regions of the spine.—Mr. H. Collinson exhibited a specimen of Acute Intussusception of the ileo-ileo-colic variety. A child, aged 2 years, was admitted into hospital with a history of obstruction for three days. The intussusception was irreducible and was resected, Paul's tubes being fixed into the ileum and ascending colon. Eight days later the openings were closed and a lateral anastomosis was performed between the ileum and the transverse colon. The child recovered.—Dr. A. G. Barrs showed a case of Cerebral Tumour in which a decompressing operation had been done.—Mr. H. Littlewood exhibited an Appendix with Multiple Diverticula.——Dr. A. L. Whitehead showed two cases of Interstitial Keratitis. The first case was that of a male, aged 15 years, with bilateral interstitial opacity of both corneæ, without iritis, of two months' duration. For six weeks the knee-joints had been swollen without causing pain or interfering with locomotion. No other evidence of congenital syphilis was present. The second case was that of a female, aged 10 years, with right interstitial opacity of the cornea, without iritis, of three weeks' duration. On examination both knee-joints were found to contain fluid. The duration of this was uncertain, since it had caused no discomfort and was unknown to the patient. With the exception of a slight scar at one angle of the mouth there was no other sign of congenital syphilis.—Dr. G. W. Watson showed a specimen of Acute Pulmonary Tuberculosis arising from ulceration of a tuberculous bronchial gland into the bronchus.—Cases and specimens were also exhibited by Mr. J. F. Dobson, Dr. T. Wardrop Griffith, Dr. J. B. Hellier, Dr. R. A. Veale, and Mr. Michael A. Teale.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held at the Great Northern Central Hospital on Nov. 10th, Dr. T. J. Horder, the President, being in the chair.—Dr. Alexander Morison showed a case of Lymphatic Leukæmia in a woman, associated with rheumatoid arthritis. The axillary and inguinal glands on both sides were much enlarged, and a blood count showed a great preponderance of white cells, of which about 94 per cent. were lymphocytes. There was no enlargement of either liver or spleen, and there was no albumin in the urine. The interesting feature of the case was the association of leukæmia with a rheumatoid enlargement of the joints, a combination which Dr. Morison had not before seen.—Dr. C. M. Hinds Howell suggested the use of naphthalene tetrachloride, under which drug he had seen a case of the sort recover.—Mr. G. B. Mower White thought the glands were possibly tuberculous, and advocated the removal of some of them for the purpose of investigation.—The President considered that this was not necessary. The condition of the blood was sufficient evidence of the nature of the case. He had used naphthalene tetrachloride both in this disease and in pernicious anæmia with success. In the latter condition it was particularly valuable in doses of 5, 10, or 15 grains thrice daily.—Mr. Mower White showed two cases of Fracture of both Patellæ occurring at intervals of 10 and 13 years respectively. On all four occasions he had himself wired the patellæ, and in both cases the first operation, as shown by X rays, had been followed by bony union. This, he considered, was unusual, the wire alone generally holding the fragments together.—Dr. Hinds Howell showed a woman, aged 32 years, who for two weeks had complained of pain in the

neck and down the right arm, and increasing weakness in the arm. There was slight paresis, most marked in the extensors of the fingers. There was tactile anæsthesia in the root areas of the third cervical to the fourth dorsal, and analgesia in those of the seventh cervical to the fourth dorsal roots. In the joints up to the shoulder there was loss of sense of position. The deep reflexes were brisk. The left plantar reflex was normal, the right doubtful. The pupils were equal and reacted well. There was no definite history of syphilis, but there had been three miscarriages. There had been no injury. The case was probably one of root neuritis, possibly of specific origin, or due to the pressure of a diffuse growth involving the posterior roots. The definite distribution of the areas of sensory disturbance precluded the idea of hysteria.—The President showed a man, aged 48 years, who gave a history of repeated attacks of Hæmatemesis and Melæna extending over eight years, the last attack having occurred at the end of October. On admission the temperature was increased, but had since fallen to normal. There had been no pain or vomiting since admission, though there had been some slight melæna. There were no signs whatever in the abdomen and neither liver nor spleen was enlarged. The patient was extremely pale, the blood examination showing the presence of a profound secondary anæmia. The absence of pain and physical signs and the long history seemed to point to the presence of a chronic gastric ulcer in the lesser curvature, and this, though not malignant at first, was now probably becoming so.—Mr. Mower White advised exploration, and thought that the ulcer was in the region of the pylorus.—Dr. Morison was of the same opinion, and the President, in replying, said that he would advise operation, though gastro-enterostomy was not always a cure in these cases.—Mr. H. E. Whitehead showed a case of Bilharziasis in which ova had been found in the urine after two years' hæmaturia. Two ova were exhibited by Mr. E. H. Shaw under the microscope.

CLINICAL SOCIETY OF MANCHESTER.—This society held its monthly meeting on Nov. 15th, Mr. J. Howson Ray, the President, being in the chair.—A discussion on Bronchitis was opened by Dr. P. R. Cooper, dealing with adults, and Dr. C. Christopher Heywood, dealing with children.—Dr. Cooper, in introducing the discussion, remarked that probably in nearly every instance bronchitis was caused by micro-organisms. A large number of these had been described, having been obtained from the secretions during life or from the bronchi shortly after death. Impure over-heated air, fogs, and noxious fumes probably acted by lowering the local and general resistance and favouring the growth of these organisms. In chronic bronchitis, especially when accompanied by bronchiectasis, the chest was a breeding ground of micro-organisms, and on the slightest provocation infections occurred, producing attacks of acute bronchitis and peribronchitis, &c. In diagnosis the causal organism must be determined, as well as the fact of its location in the bronchi, and here the services of a skilled bacteriologist were necessary. In treatment in the future it was probable that vaccine therapy might prove of great assistance, especially in the more chronic cases. The experiences of Dr. A. Latham and Dr. H. A. Des Vœux as recounted in the discussion on vaccine-therapy at the Royal Society of Medicine were quoted in support of this view. The more orthodox methods of treating bronchitis, especially in the acute stage, were briefly referred to.—Dr. Heywood briefly described the anatomical peculiarities of the chest of young children. In considering the predisposing causes of bronchitis he laid especial stress on the want of fresh air and sudden changes of temperature—e.g., from a stuffy nursery to a cold bedroom. He also urged that there should be no delay in removing adenoids if present, even during the bronchitic attack if necessary, and stated that he had seen striking relief afforded by this procedure. He then discussed the treatment by drugs, and urged the avoidance as far as possible of the usual expectorant mixtures and the substitution of emul. ol. ricini or emul. ol. morrhuæ, according to age and circumstances.—The following took part in the discussion: Dr. J. Price Williams, Dr. A. T. Wilkinson, Dr. W. A. Helm, Dr. A. A. Mumford, Mr. A. H. Norris, Dr. J. Rust, and Mr. Arnold Gregory.—The President referred to a case of Dr. Heywood in which he had removed adenoids during the bronchitic attack with most excellent results.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Nov. 4th, Mr. F. Lace, the President, being in the chair.—Cases and specimens were shown by Mr. Forbes Fraser, Dr. Norman W. Steinberg, Dr. A. J. Bruce Leckie, and Dr. Rupert Waterhouse, the latter of whom showed the two adrenals, into which hæmorrhage had occurred, of a well-nourished unvaccinated child, aged 8 months, who died after an illness of about 12 hours, characterised by drowsiness, vomiting, râles in the chest, and a blotchy hæmorrhagic eruption on the trunk, arms, and thighs.—Dr. G. E. Bowker read a paper on the Roentgen Rays in Relation to Diagnosis, dwelling more particularly upon their use in the early recognition of pulmonary tuberculosis and in the detection by their aid of renal calculi, at the same time showing an interesting group of skiagrams which he had taken illustrative of the subject matter.—Dr. Waterhouse read a paper, under the title "Anterior Crural Neuritis," on five cases in which symptoms occurred in the area of distribution of the lumbar plexus with an absence of evidence of pressure thereon. All the patients were men between the ages of 52 and 76 years. Etiological factors appeared to be gout, glycosuria, and exposure to cold and wet. Pain, the only sensory symptom, subjective or objective, was chiefly felt over the dorsum ilii, the front of the thigh, at a point a little above the middle of the shin, and on the inner side of the dorsum of the foot. There was weakness of the muscles which flex and adduct the hip and extend the knee, with resulting difficulty in mounting stairs, in rising from the sitting position, and in crossing one leg over the other, together with on walking a sense of insecurity about the knee-joint which was apt to unexpectedly flex. The objective symptoms consisted of coldness of the surface of the affected thigh, wasting of the muscles of the front and inner side, loss of the knee-jerk, and, in some instances, of the cremasteric reflex on the affected side. In two patients, who continued to walk about, symptoms referable to the knee-joint arose which were explained as the result of internal traumatism in consequence of the weakened quadriceps failing to keep the capsule of the joint taut during movement, so that the synovial membrane was apt to be pinched between the femur and tibia. The outlook in this form of neuritis, even in diabetic cases, was good.

Reviews and Notices of Books.

The Prevention of Malaria. By RONALD ROSS, C.B., LL.D. Aberd., F.R.S., F.R.C.S. Eng., D.Sc. Dub. and Leeds, D.P.H., Major, I.M.S. (retired), Nobel Laureate. With Contributions by Various Authorities. London: John Murray. 1910. Pp. 669. Price 21*s.* net.

THE student of malaria in all aspects will find in this work the most complete exposition of the subject in medical literature. Major Ronald Ross has written an admirable summary of the whole matter up to date, telling of the discovery of the parasite of malaria, summarising the facts regarding it and its mode of infection, and repeating the fundamental observations and experiments showing the part played by the parasite, the parasitic invasion in man. Finally, he gives a *résumé* of the possible preventive measures, and has called to his aid experts in the matter from divers regions of the world.

Major Ross first deals with the history of malaria. We here find the discoveries of A. Laveran, C. Gerhardt, and C. Golgi detailed. Then he proceeds to an account of the researches regarding the mode of infection, in which he has played so notable a part. In 1894 Sir Patrick Manson informed him of his new mosquito hypothesis whilst on leave in England, and on return to duty Ross at once determined to work out the whole subject thoroughly. Only those who have laboured at scientific work in India can form any just idea of the magnitude of the task. For a long time Ross worked with the wrong kind of mosquito and had many other fundamental troubles, but at length he

discovered the really culpable anopheline, and once for all determined the truth of the hypothesis.

A valuable summary of facts regarding malaria is presented to us, including facts about mosquitoes, personal prevention and public prevention, after which the evidence that the parasites are really the cause of the disease is given. This consists in such facts as the following: The parasites are not found in those who have not suffered from malarial disease; they can always be found in a large proportion of malaria cases; the patient's fever begins at the moment when the spores of the parasites are liberated—an important fact discovered by Golgi; the different types of malarial fever are caused by different species of parasites; both parasites and fever may be reproduced in healthy persons by the inoculation of infected blood; both may be reproduced in healthy persons by the bite of an infected mosquito; the severity of the illness depends roughly on the number of parasites present; certain secondary symptoms are caused by the accumulation of the parasites in certain organs; whilst, finally, quinine reduces both the parasites and the fever, and both tend to disappear in a locality if the carrying anophelines are greatly reduced in number. Major Ross then relates the result of experimental blood inoculation, and gives numerous illustrations showing the onset of malarial fever in human subjects after inoculation with the blood of patients suffering from the disease, whilst the proof of the theory is clinched by the illustrations given to show the result of experimental mosquito inoculation. One of the most striking illustrations of this occurred at the Tropical School in London, in which the late Dr. P. Thorburn Manson was bitten by a mosquito fed on a case of double benign tertian in Rome, which after biting Dr. Manson gave him fever with benign tertian parasites in his blood. He had previously not been out of England.

The author next considers the parasitic invasion of man, and calculates that to produce the first illness there must be at least 1 parasite to 100,000 hæmatids, or 50 in each 1 c.mm. of blood. With respect to the period of incubation, in the case of P. vivax, it is probable that the illness would begin on the twelfth day after inoculation. Many other points are considered in this relation, such as those concerning the further progress of the invasion after the commencement of the fever, the decline of the invasion, the appearance of sexual forms, and the facts concerning rallies and relapses. The consideration of the average duration of untreated cases and the effects of quinine make valuable reading here.

A very important section of the subject is that treating of the mortality and cost of malaria. That this is of great importance is at once evident if we take the experience of Mauritius for an example. Here there are about 39,000 adult male coolies on the sugar estates, of whom 15 per cent. are incapacitated by malaria for three months in the year—that is to say, more than 500,000 days' work are lost annually. The day's work is worth 1/4 rupee to the coolies and 5/4 to the planters; thus the coolies lose about 125,000 rupees and the planters about 625,000 rupees per annum, or 750,000 rupees together. There are besides the losses of the female coolies working on the estates and those of the Indian coolies outside the estates. With hospital and other expenditure Dr. Bolton, the medical officer of the immigration department of Mauritius, estimates that malaria costs Mauritius, with its population of 383,000, about 1,000,000 rupees a year. Using similar arguments L. O. Howard estimates that malaria costs the United States Government $100,000,000 a year.

The last chapter, contributed by Major Ross, is on prevention. In this he considers the list of possible preventive measures. In the protection against the bites of mosquitoes the necessary points to be observed as regards mosquito nets are minutely given; portable mosquito-proof rooms, fixed mosquito-proof rooms, mosquito-proofing of windows and doors and verandahs, protection for the hands and feet, medicinal protectives of the skin, and other remedies are commented on. The inquirer is also told how to effect mosquito reduction by the hand net, by fumigation, by the introduction of the natural enemies to the mosquito, and by the destruction of larvæ. Next are detailed the methods for rendering localities or houses less suitable for mosquitoes or their breeding. Succeeding these measures comes that of prevention by treatment; with respect to that by quinine Major Ross teaches that daily dosage is better than intermittent dosage. This chapter concludes with the complex subject of public malaria protection, and the medical reader is advised to make himself familiar with a difficult and contentious subject.

The special contributions of the various colleagues whom Major Ross has summoned to his aid now follow. The articles are written by experts, such as Professor L. O. Howard for the United States, Colonel W. C. Gorgas for Panama, Sir R. Boyce for the West Indies, Professor A. Celli for Italy, Mr. H. C. Ross for Egypt, Professor T. Takaki for Formosa, Colonel C. H. Melville, R.A.M.C., and Major C. E. P. Fowler, R.A.M.C., for the troops in war and peace. We make no futile attempt to note even the more important points brought out in their excellent and lucid expositions. The work concludes with certain addenda, such as a suggested terminology for the phenomena of cytogenesis, notes on the malaria-bearing anophelines, and on certain microscopic techniques. A comprehensive list of works connected with the subject completes the volume.

This is a thoroughly sound and comprehensive treatise; Major Ross and his colleagues have turned out work worthy of their high reputations.

Die Direkte Laryngoskopie, Bronchoskopie, und Oesophagoskopie. Ein Handbuch für die Technik der Direkten Okulären Methoden. (*Direct Laryngoscopy, Bronchoscopy, and Œsophagoscopy. A Handbook of the Technique of Direct Ocular Methods.*) Von Dr. med. et phil. W. BRÜNINGS, Privatdozent an der Universität Freiburg i. Br. With 37 illustrations in the text and 35 figures on 19 plates. Wiesbaden: J. F. Bergmann. 1910. Pp. 405. Price M.14 (or 14*s.*).

A LARGE circulation may be confidently anticipated for this work, seeing that it embodies the most recent developments in the technique and armamentarium of the new endoscopy of the air-passages and gullet. The product of the pen of Dr. Brünings, one of Professor Killian's most distinguished disciples, its teaching will be accepted as authoritative to an unusual degree, based, as it is, upon experience second to none in the world.

The book is divided into two main sections, the first of which, highly technical in character—perhaps too highly technical—deals with the optics and mechanics of the instruments, while the second section contains a description of the various methods of investigation and of the discoveries, anatomical and physiological, which have accrued. Although the evolution of bronchoscopic method occupies so recent a period that to write its history seems for the moment superfluous, we nevertheless welcome Dr. Brünings's account chiefly because it is through his own and Professor Killian's inventive powers that the method has come so near to perfection in so short a time. Indeed, to single out any particular stage in the progress of events for remark as showing the influence of the Freiburg workers would be impossible, for the imprint of their hand is everywhere.

Coming to the second and larger part of the book we would refer with satisfaction to the useful summing-up of the best methods of producing anæsthesia, the importance of which

with regard to successful endoscopy it is impossible to overestimate. In this connexion the reader will be interested to note the high value Dr. Brünings places upon the hypodermic injection of adrenalin in cocaine poisoning (pp. 154 and 173). Having disposed of these introductory matters the author proceeds to deal systematically with direct laryngoscopy, upper and lower bronchoscopy, and œsophagoscopy, in the course of which he finds room for a valuable chapter upon the special difficulties which arise in examining children. To the most delicate of all these endoscopic manœuvres, that of bronchoscopy, many pages are dedicated, and if at the end we have not read ourselves into perfection the fault does not lie with the author, whose directions for overcoming incidental as well as inevitable difficulties are minute and careful in the extreme. A chapter on œsophagoscopy completes a volume which for tastefulness of appearance no less than for method and thoroughness reflects the greatest credit upon the author and publisher alike.

We hope that a translation will soon be forthcoming, as the book is one of immediate interest to all medical men, and in spite of the practical character of the subject English readers will find its study in the original by no means a light and easy task.

Œdema: A Study of the Physiology and the Pathology of Water Absorption by the Living Organism. (The 1909 Nathan Lewis Hatfield Prize Essay of the College of Physicians of Philadelphia.) By MARTIN H. FISCHER, Professor of Pathology in the Oakland School of Medicine, California. Republished from the Transactions of the College. With 51 figures, including full-page plates. London: Chapman and Hall, Limited. New York: John Wiley and Sons. 1910. Pp. 209. Price 8*s.* 6*d.*

THE problem of œdema—the problem of the presence of abnormally large amount of water in tissues and tissue spaces—is part of the greater problem why protoplasm holds any water at all and why its amount is so nearly constant in normal circumstances. The author's fundamental proposition is that the cause of œdema resides in the tissues—a proposition he holds to be proved by his experiments on the absorption of water by the legs of frogs in the absence or suppression of the circulation, so that "all conceptions of œdema which regard the pressure, *per se*, of circulating fluid, as one of the causes, or the chief cause, in the development of this condition, are robbed of their most fundamental support." The author then proceeds to observations on colloid with records of experiments of the swelling of fibrin and gelatin—emulsion colloids—in various solutions somewhat on the lines of Ostwald's scheme. To show the analogy between the swelling of certain colloids—e.g., fibrin—and the swelling of protoplasm the author cites a number of similar experiments on muscle, and he comes to the conclusion that his experiments justify the view that the absorption of water by muscle is determined in the main by the state of the colloids contained in the muscle itself. Similar experiments made on the excised eyes of sheep and oxen—the latter he calls "a beef eye"—lead him to the same conclusion.

He then proceeds to discuss the biological significance of his results, and at once dismisses all vitalistic theories as to the absorption of water, and, of course, in the light of his earlier cited experiments, discards the pressure theory. To the plant physiologists he ascribes the honour of giving the earliest and best contribution towards a physico-chemical analysis of the forces active in the absorption and secretion of water by living tissues.

The author next gives a full account of cell membranes—permeable, semi-permeable, and lipoid. He seems to find little reason for accepting the osmotic theory as of paramount or even great importance in the explanation of the ways and means by which tissues absorb or secrete water. After pointing out the importance of acids and alkalies in this connexion, he comes to his main contention that every condition that makes for a state of lack of oxygen in the œdematous parts, be this through disturbances in the affected parts themselves, or in some distant organ, as the heart, makes for an increase in the severity of the œdema. He then proceeds to explain on this supposition the œdema of glaucoma, adding a statement as to the relief in this disease obtained by the subconjunctival injection of sodium citrate. Œdemas of the kidney, liver, and lungs are next dealt with. There is an interesting chapter on turgor, plasmolysis, hæmolysis, and allied phenomena, and one on the secretion of urine.

The essay altogether abounds in ingenious suggestions and we commend it to the clinicians and pathologists, but above all to the experimental physiologists and pathologists. There are several illustrations of œdematous frogs, and many curves in the text, but there is no index.

The Fats. By J. B. LEATHES, M.A., M.B. Oxon., F.R.C.S. Eng., Professor of Pathological Chemistry in the University of Toronto. (Monographs on Bio-chemistry.) London: Longmans, Green, and Co. 1910. Pp. 138. Price 4*s.* net.

THE latest of the excellent series of Monographs on Biochemistry is that on "Fats," which will prove useful alike to the chemist and physiologist. The fats form a group by themselves which does not overlap that of the carbohydrates or of the proteins, and can hardly be said to be of less physiological importance than either of these. The author deals first on the usual lines with fatty acids saturated and unsaturated, with glycerol and glycerides, other alcohols, and their fatty esters. To compounds consisting of fatty acids and containing phosphorus and nitrogen he gives the name of *Phospholipines*, which group contains some of the substances obtained from the brain by Thudichum and called by him "phosphatides." The lecithines are fully described. *Galactolipines*—e.g., cerebrone—are compounds of fatty acids that contain nitrogen and galactose, while the lipines contain nitrogen but no phosphorus or carbohydrate group. Chapter II. deals with extraction and estimation of fats in animal tissues. A few diagrams of apparatus might help the reader. The last chapter, on the Physiology of Fats, is the one most interesting both to the biologist and bio-chemist as it deals with the synthesis of fats and their higher fatty acids, the physiological oxidation of fats, and the rôle of fats in vital phenomena. There is an excellent and full list of original papers.

We can cordially commend the perusal of this monograph to the bio-chemist and to the physiologist.

LIBRARY TABLE.

The Histogenesis of the Blood Platelets. By JAMES HOMER WRIGHT. (Publications of the Massachusetts General Hospital.) Reprinted from the *Journal of Morphology*, Vol. XXI., No. 2, July, 1910. With two coloured plates. Pp. 16.—Among all the constituents of blood, the blood platelets have probably been the subjects of more divergent theories than any others. Some of the suggestions as to their origin put forward in the past may well be dismissed at the present time as is indicated by Dr. Wright in the paper before us. For instance, he gives good reasons why the theory which attributes the origin of the blood platelets to the extruded nucleoli of the red corpuscles is not correct. There are in this case other reasons not mentioned by Dr. Wright which are still more conclusive, for there is considerable evidence to show that the nuclei of the red corpuscles are never extruded *en masse* under normal conditions.

Dr. Wright in the present paper traces the origin of the blood platelets to detached portions of the cytoplasm of certain giant cells found in the blood-forming organs which he calls "megakaryocytes" after W. H. Howell. One of the weak points in his argument is that the only way in which the granules in the blood platelets and the "megakaryocytes" can be demonstrated is by using a particular method of fixation and staining. There are points about the technique which would probably not meet with the approval of those who have devoted themselves to the study of cells. Moreover, though it is quite probable that there may be constituents of cells which can only be demonstrated by one special method of fixation and staining, the experience of cytologists in recent years has shown that many cases in which a particular method was accepted as necessary to demonstrate a particular cell constituent were due to some mistake. For instance, the various parts of trypanosomes were supposed to be hardly stainable by any other method than Romanowsky. It has since been shown that if the films are not dried differential staining of trypanosomes by almost any of the regressive methods is quite easy.

The Microscopical Diagnosis of Diseases of the Blood and of Pathological Tissues. By O. C. GRUNER, M.D. Lond. London: George Pulman and Sons, Limited. 1910. Price 2*s.* 6*d.*—This is the fifth volume of the Phonographic Medical Library which is being issued by the Society of Medical Phonographers, and is intended both for the practitioner and student who reads phonography. The first section of the little book deals with the diagnosis of diseases of the blood and draws special attention to the blood-count and to the identification of the pathological appearances of blood cells. A useful glossary of terms used in hæmatology closes a clear though brief account of an interesting subject. The second half is devoted to the diagnosis of morbid tissues and the preparation of specimens for the microscope, and contains an appendix giving some useful fixing and staining formula. Two plates, beautifully reproduced in colour, show the microscopic appearances referred to in the text. On account of the desire of the author to make this volume uniform with those that have already been issued in the series, his treatment of the subject has been somewhat limited, but in his preface he states that he has in view the publication of a "longhand" version which may be a little fuller. We have often pointed out the value of a knowledge of shorthand to both practitioner and student, and the work under notice, while useful as a reading book, will at the same time add to the knowledge of the medical phonographer.

The Inherent Law of Life. By FRANZ KLEINSCHRODD, M.D. Translated and edited by LOUISE C. APPEL, M.B.Lond. London: George Bell and Sons, Limited. 1910. Pp. 214. Price 3*s.* 6*d.* net.—The author and translator of this book state that the former is acquainted only with "modern" or "Western" science, while the latter has the advantage of being a Theosophist and of having studied "ancient" or "Eastern" science." We have found no "science" in the English version, and may fairly infer that the quest for it in the original German would be equally vain.

Woman and Marriage: a Handbook. By MARGARET STEPHENS. With a Preface by Dr. MARY SCHARLIEB, and an Introduction by Mrs. S. A. BARNETT. London: T. Fisher Unwin. 1910. Pp. 280. Price 3*s.* 6*d.* net.—This book adds one more to the large number of works already in circulation on the subjects named in the title, and it is a good example of its class. Mrs. Stephens treats the difficult subject of the initiation of children into the mysteries of sex with delicacy and good sense. She inclines to the opinion that it is a mother's duty to tell her children what is necessary. Many hold that it is better left to a wise and discreet schoolmistress, as a subject, perhaps, to be included in lessons, but there is room for both opinions. Any way, the information is probably best imparted in stages beginning at an early age, and if this were the case there would not be so many wedding night tragedies, nor would the interview between mother and daughter so painfully, and yet amusingly, described in "Autour de Mariage," be necessary. Mrs. Stephens's remarks upon the hygiene of early womanhood, marriage, pregnancy, and labour deal with the matter both from the mental and physical view and are trustworthy. Although we quite endorse the statement that tight clothing is injurious during pregnancy, we cannot agree with the remark: "The very meaning of the word at present so much used (*enceinte*) is 'ungirdled.'" As a matter of fact, it is exactly the opposite. Neither do we think that the statement on p. 71 that the chick finds its nourishment almost entirely in the white of the egg during incubation is correct. Except for these slips the book should prove of use to those for whose instruction it has been written.

The Faith of an Evolutionist. By THEOBALD A. PALM, M.D. Edin. London: H. R. Allenson, Limited. 1910. Pp. 159. Price 2*s.* 6*d.* net.—The book is an undoubtedly sincere attempt to show how the author harmonises his own conceptions of evolution and religion. But his conception of evolution is very vague; and he uses this term in any sense which seems to help him in maintaining his view that a belief in evolution is an assistance towards the acceptance of religious mysteries. The following instances will suffice to show that the book is in no sense scientific. In one place he calls in "the evolutionist's axiom," that all life proceeds from a previous living being, to strengthen the belief in a Divine Creator. In another place he quotes the Atonement as presenting to the evolutionist "the supreme instance of the struggle for the life of others." The world's hero, he says, is one who wins in the struggle at the expense of others; the Christian hero is he who lays down his life in the struggle. Illustrations of this kind abound in this little book, the author of which is clearly gifted with sincere faith as well as with some degree of poetical imagination.

JOURNALS AND MAGAZINES.

Jahreskurse für Ärztliche Fortbildung. (*An Annual Post-graduate Course.*) A monthly journal. Munich: Lehmann. Price M. 16 per annum.—The September number is devoted to orthopædic surgery and affections of the locomotive organs. Professor Lange writes on spinal deformities and infantile paralysis. The details of the treatment of tuberculous spondylitis by the moulding of a plaster bed and the different forms of plaster jackets and corsets are carefully described. A novel and ingenious operation for preventing a spinal deformity due to tubercle from becoming worse is mentioned. It consists of the incorporation of two steel bars, 10 to 14 cm. long and of the diameter of a pencil, into the vertebral column. These act as internal splints and are left permanently in place, one case which is figured having had the operation two years previously. For the treatment of tuberculous abscesses, aspiration with injection of iodoform is recommended in preference to the use of the knife, but it is admitted that this must usually be repeated and Beck's bismuth injections are advised if a fistula results. In dealing with the subject of laminectomy for tuberculous paraplegia, it is mentioned that Chipault in 103 cases only obtained success in 25. Infantile paralysis and the treatment of its resulting deformities take up a large section of this number. In the acute stage of the disease a plaster mould to keep the spine at absolute rest is advised. The following methods of treatment are then carefully detailed with a judicious selection of the points of cardinal importance: the use of apparatus for the prevention of deformity, forcible

correction of established deformities, nerve-grafting, arthrodesis, tendon transplantation, and some recent improvements in the construction of artificial limbs. The author states that he has not yet seen any satisfactory result from nerve-grafting. It is advised that arthrodesis in the knee should not be undertaken until after 20. Professor Ludloff, in dealing with the affections of the locomotive organs, confines himself almost entirely to a consideration of the hip-joint. He first gives the differentiating signs of the various injuries and diseases of this joint, and then discusses the best methods of its systematic examination. A great number of very clear diagrams illustrate his points, and the whole article will be of the utmost value both to students and practitioners.—The October number deals with the subject of infectious diseases. Professor von Jaksch gives a short reference to the most important of the 500 papers referring to this subject that have appeared during the year. This heroic attempt results in his article being so condensed as to consist of little more than a reference list of current literature. There is held to be sufficient evidence for regarding Bordet's bacillus as the specific cause of whooping-cough. In scarlet fever the white blood cells show certain alterations, consisting of an increase in the number of polynuclear cells, a diminution in the lymphocytes, and an increase in the eosinophile cells. There also occurs a well-marked chlorine retention, which is held to have an important relation to the occurrence of nephritis. When treating of enteric fever the existence of typhoid carriers is regarded as having the greatest importance in the propagation of the disease. Amongst tropical diseases the following are reviewed at the greatest length: kala-azar, beri-beri, sleeping sickness, and malaria. In relation to tuberculosis an account is given of the value of antiformin in the examination of sputum and fæces. Its use is to render the detection of small numbers of the bacilli easy by segregating them out of a large bulk of fluid. Citation of 140 recent papers makes this article a most valuable work of reference. Professor Fraenkel occupies 17 closely filled pages with an explanation of the nature and phenomena of anaphylaxis or the hyper-excitability of immunised animals to further doses of the immunising agent. "Anaphylaxis is thus a form of auto-intoxication, brought about in this manner, that the anti-albumin bound to the cells in the circulating blood and other tissues combines with freshly introduced albumin and thus sets up the phenomena we have been considering. Anaphylaxis must therefore be regarded as a peculiar form of albumin-anti-albumin reaction which may occur in the living body as well as in the test-tube." He next deals with typhoid fever. It is pointed out that the modern view of this disease is more and more that of a blood infection rather than one primarily of the digestive tract. Therefore, great importance is given to the recent methods by which the bacilli can be detected in the blood. As a preliminary to these, a comparatively large quantity of blood must be taken direct from a vein and mixed with ox-gall. Then by the use of recent methods of staining and culture, which are given in some detail, the bacilli are detected. A short reference is made to paratyphoid fever and its possible relations to meat, and especially to sausages. A long list of references is appended.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., E. A. MINCHIN, M.A., and GILBERT C. BOURNE, M.A., D.Sc., F.R.S. With lithographic plates and figures in the text. New series, No. 220 (Vol. LV., Part 4). November, 1910. London: J. and A. Churchill. Price 10*s.* net.—This part contains: 1. The Division of the Collar-cells of Clathrina Coriacea (Montagu): A Contribution to the Theory of the Centrosome and Blepharoplast, by Muriel Robertson, M.A., and E. A. Minchin, M.A., with plates 25 and 26. In this article the authors discuss at some length the significance of the blepharoplast and the centrosome, which they consider to be bodies of essentially the same nature. They define a trypanosome as a binucleate organism, possessing a trophic nucleus, a kinetic nucleus, and a blepharoplast, or basic granule. With the view of throwing light on various disputed points they have studied the division of the collar-cells of a calcareous sponge. 2. Studies of Avian Hæmoprotozoa: (1) On Certain Parasites of the Chaffinch (Fringilla cœlebs) and the Redpoll (Linota rufescens), by H. M. Woodcock, D.Sc. Lond., assistant to the University, Professor of Protozoology, with plates 27–31. This is an attempt to obtain some enlightenment on the important question of the life-cycle of the avian hæmoprotozoa. The article is a very long one. The author finds the medium best adapted for preserving the parasites in life, and to enable them to propagate, is the blood-agar medium, the blood being derived from the rabbit or from the ox. The principal habitat of the trypanosomes is in the marrow of bones. Very full details of the parasites are given, illustrated by numerous figures. 3. Studies on Ceylon Hæmatozoa; No. II., Notes on the Life-cycle of Hæmogregarina Nicoriæ, Castellani and Willey, by Muriel Robertson, M.A., with plates 32–41 and one text figure. These observations by Miss Robertson give, she observes, somewhat fuller accounts than those given by Dr. Castellani and Dr. Willey published in the *Quarterly Journal of Microscopical Science.* 4. On the Origin and Migration of the Stinging Cells in Craspedote Medusæ, by Charles L. Boulenger, M.A. Camb., lecturer on Zoology in the University of Birmingham, with plates 42 and 43 and 5 text figures. This part contains also the table of contents and index to Vol. LV.

CHARING CROSS HOSPITAL.—We have received from Lady Juliet Duff an appeal for £100,000 in order to free Charing Cross Hospital from debt and enable the wards at present closed to be reopened. There are five wards, containing 87 beds, which are closed for lack of funds, and apart from the 1500 sick persons which it is estimated are thus debarred from treatment, a large number of casualties that ought to be treated at the hospital frequently have to be sent to other institutions. Lady Wantage has promised £1000 towards the appeal fund and Messrs. N. M. Rothschild and Sons have given £300. Donations, which may be sent either to Charing Cross Hospital or to 51, Portland-place, London, W., will be gratefully acknowledged by Lady Duff, who is president of the appeal committee.

WANDSWORTH SCHOOL CLINIC.—A meeting to discuss points affecting the treatment of school children at the Wandsworth School Clinic will be held at the Town-hall, Wandsworth, on Dec. 2nd, at 8 P.M., in order that by the coöperation of all interested the clinic may prove successful. Invitations to attend are being issued not only to all registered medical practitioners in the district, but also to all members of the school care committees and the heads of school departments. The clinic will be opened on Jan. 1st, 1911, in Garrett-lane, Wandsworth, and will be under the control of the Wandsworth division of the British Medical Association. It has received the approval of the London County Council and the Board of Education. There will be a staff of seven local medical practitioners, who will hold office for one year only and who will be succeeded by others in rotation, the selection being made by the London County Council. The clinic will be open only to children attending the Council elementary schools whose parents are unable to pay the fees of local medical men and who have been found defective after medical inspection as to the ears, nose, throat, or eyes. A nurse appointed by the London County Council will be in daily attendance. Ringworm will be treated at the surgeries of local medical practioners.

New Inventions.

A VULSELLUM CATCH-FORCEPS FOR THE MORE EFFICIENT REMOVAL OF IMBEDDED TONSILS.

THE accompanying illustration depicts the forceps which Messrs. Mayer and Meltzer, 71, Great Portland-street, W., have made to my design for assisting in the removal of large tonsils which do not project beyond the level of the faucial pillars. Under such circumstances, and even when pressure is applied from without, the "guillotine" will only succeed in removing slices of the tonsils and will not get rid of the most important part of the gland—viz., its upper portion, which is intimately associated with the supra-tonsillar fossa, a region in which many of the acute, and most of the chronic, inflammations of the tonsil take their origin. By means of these forceps the enlarged gland can be securely seized and drawn inwards and forwards, while with scalpel or scissors the faucial pillars may be freed from the gland substance, its capsule entered, and the tonsil more or less turned out of its bed. When thoroughly freed from surrounding structures the ordinary guillotine or tonsil snare may be slipped over the forceps and the tonsil completely enucleated.

The advantages of the instrument are twofold: 1. It is slightly curved towards the claws, so that the surgeon's view is not obstructed, as is the case with a straight instrument. 2. Once the tonsil is securely grasped it is not released until the operation is completed—a great advantage over the old vulsellum forceps with scissor handles.

Harley-street, W. HERBERT TILLEY, F.R.C.S. Eng.

"WIGMORE" NASAL DOUCHE.

Messrs. Allen and Hanburys are making for me a simple rubber contrivance for irrigating the nasal passages which they have registered as the "Wigmore" nasal douche. I have made use of the douche for some months in my practice and find it answers admirably. It has the following advantages:—1. Children use it easily and without making

a mess; its simple appearance does not cause them alarm. 2. The lotion passes at inspiration through the nasal passages without discomfort or shock. 3. A good quantity of lotion can be employed, as is often necessary, without danger to the Eustachian tubes. 4. There is nothing to break, and the douche can be easily cleaned or sterilised.

I have found the douche very useful in treating common nasal catarrh, the lotion employed being a weak solution of common salt and carbonate of soda. Those who suffer from attacks of "cold in the head" will find a daily irrigation with some such simple lotion an excellent preventive measure.

Croydon. A. PERCY ALLAN, M.D. Lond.

NATIONAL DENTAL HOSPITAL.—On Nov. 18th, under the presidency of Mr. Butlin, President of the Royal College of Surgeons of England, the staff and past and present students of the National Dental Hospital spent a very pleasant evening at the Trocadero Restaurant, at Piccadilly-circus, London, W., the occasion being the annual dinner and the presentation of prizes and certificates to the successful students by the chairman. In addition to the chairman, the guests present included Mr. W. B. Bacon, Dr. Dudley Buxton, Mr. C. A. Clark, Mr. P. P. Cole, Mr. J. F. Colyer, Mr. W. H. Dolamore, Mr. F. S. Eve, Mr. Clinton T. Dent, Mr. C. W. Glassington, Mr. W. A. Maggs, Sir Henry Morris, Mr. S. H. Olver, Mr. P. H. Parsons, Mr. W. B. Paterson, Mr. C. F. Rilot, Mr. William Rushton, Dr. H. Campbell Thomson, and Professor A. S. Underwood. The toast of the evening, which followed that of "The King," was proposed by Mr. Butlin, who, in an interesting speech interspersed with personal experiences and amusing anecdotes, set forth the wonderful advance which the dental profession had made in the past 50 years. The quack, he said, was always able to make the public believe that he knew more than the professional man, and to illustrate the gullibility of the public the speaker recalled the written statement of a quack trading under the name of Cosmos, whose firm stopped teeth "which were set with diamond pivots and fitted with emeralds, the work being done with steam, which is well known to be the most efficacious method." In order to show the progress of the past half-century he pointed out that Cartwright in an address in 1857 had said that the standard of education for dentists was calculated to form merely a successful artisan. Dentistry was frequently practised by chemists and druggists, and even a brass-turner and a blacksmith combined with their trades the extraction of teeth, while the general opinion of the public was that anyone could take out a tooth. At the present time the work of the dental profession was closely related to medicine and surgery, it had a large scientific literature, and it was recognised that the proper care of the teeth had a vast bearing on national health. Who, Mr. Butlin concluded, would have ventured in 1861, when the National Hospital was founded, to say that at the present day some of the staff of the hospital would be acting as examiners, or that a dentist would be not the least interesting Hunterian Professor at the Royal College of Surgeons. Mr. Sidney Spokes, Dean of the hospital, who responded to the toast, spoke of the need for reconstructing the hospital. The matter had been brought before the notice of King Edward's Hospital Fund and had, he understood, received the approval of that body. Dr. Campbell Thomson, the Dean of Middlesex Hospital, who proposed the toast of the "Past and Present Students," said that many of the dental students of London received part of their training at the Middlesex Hospital, and he congratulated the students on the excellence of their work. Mr. C. L. Donne and Mr. A. Barritt responded. The toast of "The Visitors" was proposed by Mr. F. R. Smyth and responded to by Sir Henry Morris, who, as a representative of the General Medical Council, said that the interest of the dental profession always received the best consideration. The following is the prize list (in addition to a certificate those marked (1) received a medal):—Dental Anatomy and Physiology: B. Mendleson (1), A. Barritt (2), P. P. Davies (3). Dental Surgery and Pathology: B. Mendleson (1), A. Barritt (2). Dental Mechanics: G. T. Davies (1), E. R. Dermer (1), G. J. S. Rose (1); W. Sampson (2), G. L. Venning (3). Dental Metallurgy: A. Barritt (1), A. D. E. Shefford (1); G. T. Davies (2), G. J. S. Rose (2); G. L. Venning (3). Dental Materia Medica: A. Barritt (1), B. Mendleson (2), P. P. Davies (3). Dental Histology: B. Mendleson (1), A. Barritt (2). Operative Dental Surgery: A. A. Hume (1), B. H. Jones (2). Ash Prize: B. Mendleson. Rymer Medal: B. Mendleson.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 26, 1910.

The Hereditary Factor in Pauperism.

AMONGST the many services which medicine has rendered and is rendering to the modern State, one of the least recognised but by no means the least important is the change of method which it is introducing into the study of social problems. It has brought to the investigation of these questions that inductive spirit which, necessary in every field of scientific inquiry, is doubly necessary when dealing with phenomena in which a real diversity of nature is very easily disguised under a superficial appearance of uniformity, and in the study of which there is therefore a corresponding liability to the fallacies that lurk in generalisation. From errors of this sort the medical observer is, or ought to be, protected, not only by the general habit of mind which he owes to the discipline of his science, but also by the fact that he naturally approaches the consideration of these social problems through the study of individual instances, and for that reason is under no temptation to overlook the heterogeneity of the phenomena which each of these problems embraces. In the result this means that the influence of medical science on sociological inquiry is to make it primarily biological, and this not merely in the sense of allowing in the general view for the operation of biological forces, but also in the sense that it bases the investigation of social phenomena on the study of the living individualities which make up the social group. In short, the inductive spirit forces us to recognise that from the varying characteristics of these individuals and from their varying response to and reaction upon environmental agencies the social phenomena result, and not, as is the assumption of *a priori* sociology, from the play of economic forces on a collection of passive and equivalent units.

A striking illustration of the change in our ideas that must follow from this way of looking at social questions is furnished by the very remarkable study of the hereditary factor in pauperism which appears in the number of the *Eugenics Review* for the current month. This journal is the organ of the Eugenics Education Society, a society founded under the distinguished presidency of Sir FRANCIS GALTON, with the object, as its name implies, of educating public opinion in matters relating to the improvement of the race. Early in the present year the society appointed a small committee to consider the eugenic aspects of Poor-law relief, and as it was held that the Majority and Minority Reports of the recent Royal Commission gave practically no information on this side of the question, the committee undertook an independent inquiry, directed more particularly to determining whether pauperism is in any measure due to inherent lack of civic aptitudes, and whether therefore the tendency to become paupers is hereditarily transmitted through succeeding generations. The most important section of the report now published embodies the first instalment of the results obtained in this inquiry, and consists of an extensive pedigree of intermarried pauper families, comprising four generations and 183 individuals. This pedigree and a number of smaller pedigrees, given in a separate and very valuable paper by Mr. LIDBETTER, an experienced Poor-law official who assisted in the investigation, are the most important, and indeed almost the only, data that have yet been published with reference to this question. We may add that the inquiry appears to have been carried out with commendable thoroughness, and that the critical examination of the evidence seems to have been of a sufficiently searching character to ensure a just estimate of the relative values of the biological and economic influences in each case. It is only on the basis of a minute and detailed investigation of this sort that we can found the scientific study of any bio-social fact.

Considering now this instructive pedigree, we find that it shows very definitely certain facts which throw a good deal of light on the true inwardness of pauperism, or at all events of some forms of pauperism. First among these is the fact that pauperism tends to recur in successive generations of the same family. In one family, for instance, the youngest generation is represented by three children, two of whom (one being illegitimate) are of the hooligan type and are in an industrial school, and the third is in a workhouse school. The mother of these children was illegitimate and is a pauper, the maternal grandmother was likewise illegitimate and was a pauper, and the maternal grandfather was also a pauper, while on the paternal side the father and both grandparents were paupers. Such a history—and it is typical of a large number of the families shown in the pedigree—suggests very strongly that the pauperism which we are dealing with here may be the expression of an inherent and transmissible defect of character, and cannot be explained simply as a result of adverse economic conditions. And in support of this view we find that the committee as a result of their personal examination of these hereditary paupers describe them as presenting "obvious defects in physique and character," as "below the average in their powers of intelligence, continuity of work, and endurance," and, further, as showing these deficiencies from youth. Another trait of this class, and one which is possibly to be connected with the characteristic of moral feebleness to which we have just referred, is the frequency of illegitimacy and its apparent tendency to run in families. We may note this in the case quoted above, and in another instance in the pedigree illegitimate descent runs through four generations. It is interesting to observe that both in their free unions and in their marriages the members of the pauper family appear to have a decided preference for allying themselves with other pauper families, to such an extent indeed that the genealogical tree in its general aspect suggests a care for purity of blood hardly to be excelled by a rigidly exclusive race of the *haute noblesse*. In explaining the occurrence of this in-breeding in the pauper stock—a fact in itself by no means regrettable—

we must, no doubt, take account of the influence of association in workhouse life, but even when we have made full allowance for this factor, the tendency must be admitted to imply a want of resistance to a degrading environment which is in itself indicative of weakness of character. Another fact of interest brought out by these records has been already remarked by other observers—namely, that the degenerate tendencies do not manifest in transmission a single set of characteristics, but take on a great multiplicity of forms, so that a single family stock may produce paupers, imbeciles, feeble-minded inebriates and prostitutes, and certain types of criminals.

In the interpretation of the facts which we have briefly outlined in the foregoing remarks we have, of course, to take account of the difficulty of distinguishing between what is due to inherent disposition and what to the influence of environment. The mere fact of paupers occurring in several successive generations of the same stock, striking and suggestive as it is, is not sufficient proof of the inheritance of a specific tendency to pauperism. It may be explicable, wholly or in part, as the result of inheritance in a different sense, the inheritance of opportunity which passes on the same mode of life from one generation to another, which has been known to make writers of verse *invitâ Minervâ*, and which may lead the son of the scholar to follow in his father's footsteps, not because he has inherited his brains, but because he has inherited his library. In the present instance this fallacy appears to have been avoided by the examination of the individuals whose characteristics were in question and who were found, as we have already remarked, to show evidences of innate inferiority; but in view of the importance of the point it is perhaps to be regretted that the writers in the *Eugenics Review* have not dealt with it in more detail. In any case, however, it is likely on psychological grounds that the influence of the social *milieu* is less potent and the influence of inherent disposition more potent in conduct phenomena of the passive sort, such as pauperism, and possibly prostitution, than in more active manifestations, where an inherited environment may do much to impart a definite direction to plastic aptitudes, as is probably the case, for instance, of skilled crime or of the learned professions. These considerations will incline us therefore to adopt the view which the eugenic investigators urge on our acceptance and to conclude that the pauper class is in a large measure perpetuated by the free breeding of definite pauper stocks, the offspring of which are characterised by a native incapacity to live in any other way than as social parasites. However interpreted, the facts are obviously of very great practical importance, and in reporting them the Eugenics Education Society has done a real service to sociology.

Intermittent Limping.

A CONDITION of intermittent lameness sometimes referred to as "spring-halt" has long been known to occur in horses, and has been found to be due to aneurysmal conditions of the iliac arteries resulting from the presence of parasitic worms. The explanation usually given of the symptoms is that the condition of the vascular supply to the lower limbs is such that, while it is sufficient for the needs of those structures at rest, it is incapable of affording the extra supply required by the muscular exertion of progression. A similar condition has often been described in man under various names, such as intermittent claudication, crural angina, intermittent limping or lameness, and dysbasia angiosclerotica. CHARCOT in 1856 described a case in man associated with the presence of an aneurysm of one of the iliac arteries. It is, however, to Professor W. ERB of Heidelberg, whose researches upon many of the disorders of the neuro-muscular mechanisms are so well known, that we owe the most exhaustive and critical study of the clinical and pathological features of the disease. His original paper was published in 1898, and in it he attributed the condition to arterio-sclerotic changes in the main arteries of the lower limbs. Again, in 1904 he published a further study of the disease based upon 45 cases. Recently he has contributed an interesting analysis of 38 fresh cases, and reviewed the main features of the condition.[1] Several other papers have also appeared upon the same subject during the last few months by GOLDFLAM,[2] HANS CURSCHMANN,[3] and LEOPOLD FISCHER.[4] Both Professor ERB and Dr. CURSCHMANN maintain that it is by no means uncommon, and that in spite of its characteristic symptoms it is often overlooked or wrongly diagnosed. In many English text-books it is dismissed with but brief reference, and in view of this fact and of the gaps which still exist in our knowledge of its causation and pathology it is of some interest to review the chief features which it presents.

The main symptom of this condition is the lameness or difficulty in walking to which it gives rise. After a longer or shorter period, varying from 5 to 30 minutes, sensations of fatigue, stiffness, and cramp supervene, causing the patient to limp and eventually to come to a standstill. After a short rest he may be able to start off again, but is soon again limping and brought to rest by a return of the symptoms. With these motor symptoms there are also associated certain sensory and vaso-motor phenomena, including paræsthesia and pain in the feet and legs, stiffness and painful cramps in the calves, anæmia and coldness of the skin, or sometimes cyanosis, but rarely heat—all these phenomena developing on walking and disappearing with rest. A most important feature in these cases is that the pulse in the dorsalis pedis and posterior tibial arteries is more or less completely suppressed. In some cases only one pulse may be wanting, while in others, two, three, or all four may be weak or absent. In some cases they may vary with the condition of the feet, whether warm or cold, or with the condition of the patient. Professor ERB lays stress upon the importance of investigating these pulses in cases of neuro-muscular disease of the lower extremities, although he admits that it requires time and patience to do so. The vaso-motor phenomena are of considerable interest, the more so in view of the fact that Professor OPPENHEIM describes a functional or angiospastic form of intermittent limping depending upon vaso-constrictor excitability. This view is approved by Dr. CURSCHMANN, but Professor ERB and Dr. GOLDFLAM both express doubts as to its existence, and Professor ERB believes that such cases are really examples of intermittent limping in which the

[1] Münchener Medizinische Wochenschrift, No. 21, p. 1105, and No. 22 p. 1181.
[2] Ibid., No. 33, p. 1747. [3] Ibid., No. 31, p. 1630. [4] Ibid., No. 39, p. 2041.

arterio-sclerotic changes are not at first sufficiently marked to be recognisable. He maintains that the vaso-motor phenomena are sequels or concomitant symptoms of the condition and denies that they stand in a causal relationship. In the case recorded by Dr. FISCHER, soon after the pain in the calf and foot came on, the leg and foot became pale and corpse-like in appearance owing to a marked ischæmia, which was soon followed by an intense hyperæmia. On walking again this soon gave place to ischæmia, to be again followed by hyperæmia. This case was also of interest in that the condition was unilateral and that the vaso-motor phenomena did not develop until the condition had existed for years, thus supporting Professor ERB'S contention.

In regard to the etiology of the condition, it is remarkable that it is rare among the poorer classes, the great majority of Professor ERB'S cases having occurred in his private practice, the reasons for this being as yet obscure. It is also comparatively infrequent in women, the proportion varying from 1 woman to 16 or 18 men in certain collected groups of cases. Some statistics also suggest a preponderance of the cases among the Jews, but this is as yet uncertain. The disease usually manifests itself after the fortieth year, but cases occur earlier. Both syphilis and alcoholism appear to play a subordinate part in the production of intermittent limping, but in regard to tobacco there is a general agreement that it is an important causal factor. More than 50 per cent. of Professor ERB'S present series of cases confessed to excessive use of tobacco, and he suggests that tobacco may lead to a localisation of arterio-sclerotic changes in the limb vessels, thus confirming the statements of GOLDFLAM, STRÜMPELL, VON SCHROTTER, and others, that misuse of tobacco is an important cause of arterio-sclerosis. Exposure to cold seems also to exert an actual influence upon the causation of the disease, a history of living in cold rooms, of lying on wet ground, or of military exercise in snow, occurring in about half of the cases. Diabetes was a coexisting disease in a few of the cases. The influence of bodily and mental overstrain, of neurasthenia and other nervous diseases is as yet obscure, and Professor ERB suggests that particular attention should be paid to these conditions in recording cases. No doubt in most cases various causes combine to produce the changes in the vessels leading to intermittent limping, but among them it seems probable that misuse of tobacco plays a predominant part.

The diagnosis of the condition is a matter of considerable urgency, since it is sometimes a precursor of arterio-sclerotic gangrene, and by appropriate treatment this untoward sequel may be prevented. Among the conditions for which it appears to have been mistaken, according to Professor ERB, are various affections of the spinal cord, neuritis, myositis, venous thrombosis, myasthenia, Raynaud's disease, acro-paræsthesia, erythromelalgia, and hysterical and neurasthenic dysbasias. Dr. CURSCHMANN describes certain atypical cases in which at first the difficulty in walking became less after further effort. In opposition to ERB and GOLDFLAM, he believes in functional or angiospastic forms of the condition, and describes a case in which symptoms of intermittent limping coexisted with osteomalacia. Treatment directed to the latter condition gave complete relief to the lameness. Professor ERB also describes two cases of acute arteritis of sudden onset and of idiopathic nature occurring in previously healthy young men—in one case after exposure to cold, in the other without obvious cause. The condition was unilateral in both cases and gave rise to symptoms similar to those of intermittent limping, with absence of the pulse in the arteries of the foot on the affected side. Professor ERB has not been able to find any similar cases in the literature of the subject. The pathology in all cases seems to be an affection, usually arterio-sclerotic, of the vessels of the lower limbs.

The treatment of intermittent limping consists in endeavouring to remove the causal factor, such as the excessive use of tobacco or the exposure to cold and damp, and in applying measures directed to combat the progress of the arterio-sclerotic changes in the vessels of the limb. Various iodide preparations are recommended in medium doses, such as sodium and potassium iodides, iodipin, and sajodin, and the use of iothion locally. The diet should be carefully restricted, as in cases of general arterio-sclerosis. Galvanic footbaths are also recommended, and rest is an important factor. The use of vaso-dilator drugs has been recommended, but Professor ERB says their value has not yet been established. Dr. FISCHER, in the case to which we have already referred, found amyl nitrite a valuable palliative agent. The original explanation of the symptoms of intermittent limping is that which we have already quoted—viz., that the sclerosed blood-vessels of the lower limbs are unable to supply the increased quantity of blood required for muscular activity, but an alternative theory of vaso-constrictor spasm has been suggested to account for some of the cases. The condition of intermittent lameness is of great interest also, from the light it throws upon other obscure vascular conditions. As Professor W. OSLER has pointed out, ALLAN BURNS, as long ago as 1809, suggested an analogous explanation of angina pectoris, which under the name of the intermittent claudication theory is still widely held. In like manner some of the fleeting paralyses, paræsthesiæ, amnesias, and other conditions occurring in arterio-sclerosis have been attributed to a similar condition affecting the cerebral vessels.

The Scientific Evidence in the Crippen Case.

IN our issue of Oct. 29th, p. 1299, we published a brief account of the trial of HAWLEY HARVEY CRIPPEN for the murder and mutilation of his wife, giving, save in one direction, but the barest outline of the story, no more being necessary from us having regard to the prominence which the case, in all its gruesome details, had received in the daily press during the three investigations held respectively before the coroner, the magistrate, and the LORD CHIEF JUSTICE of England. But with the medical evidence we dealt at some length because it played an important part in the conviction of the murderer, and proved once again, as in similar revolting tragedies, what a weapon in the hands of justice the right application of scientific principles may be. Now that the convict has met his fate we think it right to make a

few observations on that evidence. CRIPPEN was found guilty of his crime on perfectly common-sense grounds—grounds which could be appreciated by those without a trace of scientific knowledge. He had the opportunity to murder his victim, an opportunity which no one else possessed; he had a powerful motive for wishing to do so; he was the last person who saw her alive; he fled from justice when suspicion was aroused; he was arrested with what must be regarded as evidence of a confession in his possession; the remains of a woman, the sex being indicated by portions of hair and raiment, were found in a house which he had occupied since 1905, enveloped in a fragment of his own attire which must have been purchased at a date subsequent to the beginning of his tenancy. These things might have been sufficient to condemn CRIPPEN, but the Crown called scientific evidence which removed from all men's minds that last shadow of doubt which might have been the prisoner's benefit. CRIPPEN, having the opportunity of purchasing hyoscine, did so, and evidence was found in the remains of the presence of more than a poisonous dose of hyoscine. The victim was known to have undergone an abdominal operation, and evidence was found in the remains that an abdominal operation had been performed. There is no case here of a verdict having gone against a man solely, or mainly, on abstruse scientific points. Every episode in the revolting story pointed directly towards CRIPPEN as the murderer, which the jury pronounced him to be, the scientific evidence falling into its place in support of other testimony. The Court of Criminal Appeal upheld the verdict uncompromisingly.

A point was made in behalf of CRIPPEN which it was inevitable that the counsel for the defence should make and which it was right should receive all possible stress—namely, that the discovery of hyoscine in the remains was largely discounted in importance by the fact that, owing to a paragraph in a newspaper, it was widely known that CRIPPEN had purchased hyoscine not long before the presumed date of the tragedy. The suggestion of course was that it was possible for the scientific witnesses to be so influenced or biassed by this knowledge as to find wrongfully in the remains traces of that which they expected to find. We were glad to see that the LORD CHIEF JUSTICE, in his impartial but deadly review of the evidence, dismissed the suggestion as of no significance. Indeed, no one who has any knowledge of the procedure followed in such a scientific investigation as was demanded of the expert witnesses for the Crown could for a moment think that the chemist, every step in whose procedure would be controlled by another investigator, could be influenced in this way. It may be pointed out that in the majority of cases of suspected poisoning the investigator possesses from the beginning a clue to what he is looking for. Sometimes the dejecta of the victim give it. Sometimes the last symptoms of the dying person indicate clearly a poison or a group of poisons. Sometimes a receptacle in the bedroom contains a poison. Sometimes a poison is found in the possession of a suspect. Lastly, and generally, the purchase of a poison is traced by the police to someone concerned in the tragedy, a thing which we must presume would have occurred in this case. Blandly unsuspecting as the authorities were in the earliest stages of the investigation, we may be perfectly certain that when they saw the nature of the crime with which they were confronted they would have made inquiries at all the druggists' shops where CRIPPEN dealt, and consequently would have come across evidence of the purchase by CRIPPEN of the hyoscine. Hyoscine, as it happens, gives very distinct reactions and, without any clue to what they were looking for, the investigators would have certainly found it; all that happened in this particular case was that they received information of the sort that is generally received, and this information in no way influenced the analytical procedure.

The excitement which a singularly sordid story caused is not pleasant to look back upon. The circumstances which conspired to arouse in so marked a degree the attention of the public were adventitious and not essential to the drama, and it showed want of public intelligence not to perceive this. The ocean race, which culminated in the arrest of CRIPPEN, described in such stirring terms in so many columns of our newspapers, was not necessary to the arrest, for CRIPPEN would have been detained at the first Canadian port on the information of the captain of the *Montrose*. Wireless telegraphy, though enlisted in the cause of justice, performed nothing that could not have been dispensed with; if there had been no Marconi installation on board the *Montrose* the arrest would have been made as certainly. Divested of its sensational trappings we have a revolting tale of lust and greed. From the forensic point of view the evidence of identification was interesting, while the employment of hyoscine as the deadly agent was a novelty.

Annotations.

"Ne quid nimis."

THE EPIZOOTIC OF PLAGUE IN EAST SUFFOLK.

THE Local Government Board has issued an official statement as to the steps that are being taken in regard to the occurrence of rat plague which has been observed in certain districts in East Suffolk. The statement confirms in detail what we were able to convey to our readers last week—namely, the activity of the department in face of an anxious situation. For several weeks past Dr. H. T. Bulstrode, one of the medical inspectors of the Board, has been making local inquiries with a view of ascertaining the extent of the disease and of securing concerted action on the part of the various authorities. With him are associated Dr. W. W. E. Fletcher and Dr. R. J. Reece, also medical inspectors of the Board, and the three inspectors are making investigations over a wide area, including West Suffolk and Essex. An expert staff under the direct supervision of Dr. C. J. Martin, director of the Lister Institute, and a practical and scientific authority on plague in its various pathological and epidemic relations, has also been engaged for some time in investigating on a larger scale the local prevalence of disease among rodents, the kind of rats predominating in the districts, and the flea parasites of these rodents. Other inspectors of the Local Government Board have also been instructed to make inquiries in various parts of England. Up to the present plague-infected rats have only been found in five districts. The inspectors of the Local Government Board report that the various sanitary

authorities are actively coöperating in taking the necessary measures, while the official statement singles out for special notice, as we are very glad to see, the energetic and valuable services of Mr. H. L. Heath, assistant medical officer of health of Ipswich, who has been specially appointed by the county council of East Suffolk to deal with the matter. The county is not a rich one, and this temporary appointment carries no proper remuneration with it. On Thursday, Nov. 17th, the President of the Local Government Board received a deputation from the East Suffolk county council, when various questions of procedure were discussed at length. Mr. Burns emphasised the need for continuous and persistent efforts on the part of local authorities as well as of individuals, who it was hoped would all coöperate in the taking of measures for the destruction of rats and the prevention of their entry into houses. The official statement of the Board concludes with the intimation that although cases of plague in man are unlikely to arise, arrangements are being made by the various sanitary authorities for the early recognition and isolation of such cases should they occur. We are glad to see that the condition in Suffolk is being treated with this reasonable gravity. There never was any cause for panic, as we pointed out several weeks ago, but it is idle not to see that a peril exists which has to be guarded against.

MEDICAL STUDENTS AND THE LAHORE MEDICAL COLLEGE.

WE learn from articles in the *Lahore Tribune* that discontent prevails at the Lahore Medical College, the principal having declined to give certificates of attendance at courses of lectures to certain students who had failed to pass their examinations, except on payment of Rs.35 for each course, amounting to Rs.350 in all. It appears to have been the case that some students who had failed to pass at Lahore had subsequently come to Europe, and, armed with certificates of attendance at the necessary courses of instruction, had succeeded in obtaining European qualifications. We say "European" because we are not aware whether they were English, Scottish, or Irish. It would appear unlikely at first sight that such diplomas should be more easily obtainable by natives of India than diplomas granted in that country by examiners more intimately acquainted with the intellectual and other idiosyncrasies of the students offering themselves for examination. Probably the explanation of the situation is that the student, far away from his friends and relations, does not care how long he takes in the course of qualification, or how many times he is rejected. The Lahore University authorities seem to have come to the conclusion that the practice of men coming to Europe to obtain a qualification, after having failed to do so in their own country, was not one to be encouraged; and therefore interposed some difficulty by raising the fees for attendance certificates. Not being acquainted with all the circumstances of the case, and judging only by the presentation of the matter in the *Tribune*, we are unable to come to a decided opinion, but we are inclined to think that the syndicate of the Punjab University are in the right. The cost of medical education in India is very low. As to the wisdom of this policy of providing cheap professional education there may be two opinions; but such being actually the case, the university authorities are justified in insisting that the students, who are provided with these educational advantages, should so employ their time and abilities as to pass the examinations at their own university. The fees said to be charged for furnishing attendance certificates, apparently Rs.350, or about £23, may seem to be rather high, but the expense of the educational course itself is extremely low, and we imagine the University authorities have strong reasons for discouraging Indian students who have failed to qualify in India from coming to Europe to obtain a medical diploma. With every desire to be fair to such students, we cannot see that they have any real grievance, unless they are able to show that the examinations at Lahore were not fairly conducted, and of this there is no hint in the papers before us. If able and willing to incur the expense of a journey to, and sojourn in, Europe for the purpose of obtaining a diploma they ought not to feel aggrieved at being charged some £23 for the necessary certificates of attendance at their own university.

PRISON REFORM.

THE treatment of persons convicted of crimes and sentenced to imprisonment for two years or less, or to be "imprisoned and kept in penal servitude" for three years or longer, is receiving a great deal of attention from a Home Secretary whose leader, Mr. Asquith, when he held the same office, was responsible for the appointment of the Departmental Committee of 1895 and for the various innovations and reforms which followed its recommendations. The subject is one of considerable difficulty, involving as it does the question of combining the punitive and deterrent elements of incarceration with treatment which will, if possible, leave the prisoner at the end of his term less likely to relapse into crime than when he was convicted. From this point of view, apart from the possibility of educating him as an artisan or otherwise fitting him to earn his living honestly and of instilling into his mind a desire to do so, the care of his bodily and mental health is of extreme importance and has received, and is receiving, increased attention. To the medical man without any prejudices that can be ascribed to sentimental humanitarianism it must be repugnant that a human being, even after the committal of a heinous or brutal offence, should remain in the care of the State for a period of months or years, and should return to his fellows physically weaker than when he went in, so that he is unfit for a worker's existence until he has recovered lost vigour, or that one whose disordered mental condition has escaped recognition at his trial should undergo the rigorous and necessary discipline of prison life without any distinction being made between him and his saner fellows. Probably in the recognition and treatment of degenerate and mentally unsound prisoners there is greater room for improvement of our system than in any other of its features, and apparently the subject is one which is not escaping the notice of Mr. Winston Churchill. With regard to the maintenance of the health of prisoners by a sufficient if spare diet, by attention to sanitation and by the maintenance of suitable temperatures in extreme weathers, indeed so far as the general question of humane treatment is concerned, the improvement brought about during the nineteenth century, and particularly towards its close, has been very great, but no greater, perhaps, than we might expect from the natural growth of humane sympathy in a people whose general standard of living and of education has been considerably raised during the period. At the same time, the comparative easiness of the task of improving the lot of such limited and specially situated classes as prisoners or inmates of workhouses must be admitted. The difference between their fate to-day and that of their predecessors of 100 years ago is more marked than is the case with the humbler ranks of poor but honest workers. The Annual Register for 1810, for example, records the death in December of that year of Mr. John Russell, late keeper of the prison at Gloucester, "a man who was remarkable for his kindness and humanity to those unfortunate persons who were committed to his care." The notice continues: "It is a fact not generally

known that no adequate provision is made for the support of these persons, who, were it not for the contributions of the charitable and humane, must often experience the most severe privations. To the credit of Mr. Russell, it ought to be known that he appropriated more than half his salary to this benevolent purpose, and to the humanity of the keeper and liberal contributions of a benevolent lady these poor creatures were often indebted for a comfortable meal." Of course, contemporary evidence of the horrors of imprisonmen, at a more recent period than that mentioned are plentiful, but this naive statement of the complete lack of recognition by the State of obvious duties, and the confessed absence of any system at all where now the rigidity of the system is a source of complaint, are enough to prove that if we have not achieved perfection—a difficult task—we cannot be charged with lack of progress. But much remains to be done in which the medical profession can play a part. The scientific observation of prisoners according to their mental defects and requirements cannot be carried out without medical intervention, and treatment on such intelligent lines should pave the way to a more scientific appreciation of the original causes of crime and criminality than is now possible in this country. There are no doubt many laymen who take a sympathetic interest in the subject, but the majority of those most intimately connected with meting out the punishment of crime—judges, magistrates, and counsel, or solicitors practising in criminal courts—as well as the general public, have regarded the matter with an amount of indifference which may seem no less strange to our descendants a century hence than the methods of Gloucester Gaol in 1810 do to us at the present day.

THE SEX OF A STATUE.

IN the *Burlington Magazine* for November Mrs. Strong, whose qualifications for writing authoritatively upon such matters are undeniable, has an extremely interesting paper upon the celebrated statue known as the Fanciulla d'Anzio, which was recovered from the sea some 30 years ago and purchased recently by the Italian Government, since when it has been housed in the Museo delle Terme in Rome. The purpose of Mrs. Strong's article is to set forth her reasons for believing that this statue, which has stood in so many eyes for a typically lovely female, is really a youth, and an athletic one moreover. The statue, when its early Hellenistic date was settled, was held to be that of an extremely beautiful draped girl, but at the beginning of this year Mrs. Strong herself, Signor A. Simonetti, and Dr. P. Hartwig all stated their belief that the statue was male, and Mrs. Strong summarises the evidence for what at first sight appears to be rather a perverse view. She makes out an extremely good case, though having read very carefully her arguments, in which the possible value of medical opinion is allowed, we have come reluctantly to the conclusion that it is not possible to settle the discussion one way or the other. Unless some outside proof should turn up, some actual identification of the statue as somebody's presentation of someone, we think that the sex of the Fanciulla will always remain in dispute. Offhand, no one would doubt that the figure was that of a girl, but it is hard for anyone not an experienced archæologist to dissociate such drapery as we have here, gathered in below the breasts and again at the waist, hanging low on the neck and flowing over pronounced hips, from the idea of a female figure. With regard to this drapery Mrs. Strong states that the double girding is a motive unknown in female statues, while the higher girding is peculiarly characteristic of the robed Apollos of the fourth and third century art. If this be so, the drapery tells to the archæologist exactly the opposite story that it tells to the uninitiated observer. But does everyone agree with Mrs. Strong about the peculiarity of the robing? Dr. Hartwig is quoted as having discovered a vase picture giving the desired clue to the sex of the statue, yet this picture has been recognised by another observer as a boy tricked up in female garments. It would seem that too much stress cannot be laid upon the robes. We come now to what we can see of the actual form—namely, hair, face, neck, right shoulder, and collar-bone, top of sternum, upper edge of right breast, left arm, and feet. The hair could be that of a boy or a girl. There are statues of Apollo with more definitely feminine arrangement of locks. The neck is strong and round, but it seems to us extreme to credit it with any particularly masculine muscularity. The deltoid and biceps muscles on the left side are well developed and smoothly rounded. Dr. Hartwig seems to find this limb masculine (Mrs. Strong's words are not quite clear here), but we think it might belong to girl or boy. On the right side is a well-developed shoulder and a border of the great pectoral muscle, above which is the edge of a distinct but small globular swelling. Is this the immature breast of a maiden, or the well-developed pectoral swelling of an athletic youth? Probably it is the latter. The right arm is lost just below the deltoid curve, but when complete it was certainly thrown across the chest towards the platter on which the eyes are turned, it being balanced on the left forearm. A right arm drawn tightly across the mammary region would accentuate the muscle, and this, we believe, is what has happened. But it must be repeated that in our opinion dogmatism is impossible.

THE DEMONSTRATION OF BILE PIGMENT IN BLOOD SERUM AND IN SEROUS EXUDATES.

AN interesting paper by Professor Friedrich Obermayer and Dr. Hugo Popper appears in the *Wiener Medizinische Wochenschrift* of Oct. 29th dealing with the demonstration of bile pigment and its clinical significance in disease. In a previous paper[1] they have shown that bile pigment occurs normally in human urine, and that in a series of abnormal conditions this pigment may be increased without leading to definite jaundice. Such a pathological increase occurs in heart lesions with chronic congestion of the viscera, in cirrhosis of the liver, and in some infectious febrile diseases, such as pneumonia, also in some pleurisies and in acute rheumatism. In tuberculosis, on the other hand, no increase occurs. In the present paper they record the results of an investigation of blood serum and of various serous fluids for bile pigments with certain delicate tests. The first of these is carried out by means of a reagent made up of 625 cubic centimetres of water, 125 cubic centimetres of 95 per cent. alcohol, 75 grains of sodium chloride, 12 grammes of potassium iodide, and 3·5 cubic centimetres of a 10 per cent. tincture of iodine. This reagent is allowed to flow from a pipette to the bottom of a test tube in which are about 5 cubic centimetres of the serum to be tested. In virtue of its specific gravity it collects below the serum and a sharp line of separation is visible. After a few seconds a green ring forms, the intensity of which affords a measure of the amount of bile pigment present. Another method is carried out as follows. The serum is precipitated by means of twice its volume of 95 per cent. alcohol and filtered. The filtrate is then tested by means of an alcoholic solution of iodine or of ferric chloride. The former is made by mixing together 500 cubic centimetres of 95 per cent. alcohol with the same quantity of dilute hydrochloric acid and adding 1·6 cubic centimetres of 10 per cent. tincture of iodine. The ferric chloride solution is made by adding 30 drops of a 50

[1] Wiener Klinische Wochenschrift, No. 25, 1908.

per cent. watery solution of ferric chloride to 150 cubic centimetres of 95 per cent. alcohol and the same quantity of dilute hydrochloric acid. The test consists in the appearance of a ring varying from green to blue or blue-violet at the line of junction of either reagent with the filtrate from the serum. A third method employed was that of Hedenius. This consists in adding twice its volume of 95 per cent. alcohol to about 5 cubic centimetres of the serum to be tested, and then heating to boiling after the addition of five drops of 20 per cent. hydrochloric acid. If bile pigment be present the yellow colour changes to green or bluish green. Normal human serums were tested by these three delicate methods, and they showed the presence of bile pigments. Professor Obermayer and Dr. Popper believe that the yellow colour of normal serum is in great part due to bilirubin. Horse serum is well known to be rich in bile pigment, and the same substance was demonstrable in the serum of the dog, the ox, the rabbit, and the fowl in greater or less quantity. On investigating the serum from cases of disease it was found that the pigment was increased in those conditions already mentioned in which increased bile pigment occurs in the urine. The serum of patients with nephritis, on the other hand, showed a diminution in the amount of bile pigment present amounting in some cases to almost complete absence. In some cases of chronic interstitial nephritis, however, especially in those with cardiac failure, bilirubin was present in normal amounts or even in slightly increased quantities. The method which is most available for quantitative estimation of bilirubin in serum is the test with alcoholic iodine or ferric chloride solution. Various dilutions with alcohol of the alcoholic filtrate from the serums are tested to determine the point at which a blue ring is no longer obtainable. In testing the serum from infective diseases, such as pneumonia, a bluish-red or violet colour often replaces the green or blue-green obtained in other conditions. This is in all probability due to the presence of urobilin or urobilinogen, which give a red colouration with iodine or on heating with hydrochloric acid and alcohol. The tests suggested by Schlesinger and Ehrlich for urobilin and urobilinogen were applied, and showed that normal serum contained only minute traces of these substances, whereas they were present in definite amounts in the serum of some cases with increased bile pigment, especially in pneumonia. Various serous fluids were tested for bile pigments, and without exception they were found to be present. A yellow colouration of the cerebro-spinal fluid is rare. It occurs after hæmorrhages and after inflammatory processes of long duration in the meninges. Bilirubin can also be demonstrated in the sputum of patients with pneumonia. Professor Obermayer and Dr. Popper suggest that the factor which all the conditions presenting increased bile pigment in the blood possess in common is the participation of the liver in the morbid process, whether by cirrhosis, congestion, or by acute degenerative processes, as in the acute infectious conditions.

THE MEDICAL LIBRARY ASSOCIATION.

A CONTRIBUTION to the pages of the *Library Association Record* by Mr. H. M. Barlow, assistant librarian, Royal College of Physicians of London, draws attention to the formation in England of an Association of Medical Librarians. The actual use to which many of our libraries are put convinces him that their resources are not universally known, and it is with the laudable intention of increasing the utility and number of medical libraries in this country and making known to the medical profession the resources which are available in medical literature that the Medical Library Association has been formed. In America, from small beginnings, without encouraging sympathy, and in spite of opposition and apathy, the Association of Medical Librarians is now firmly established and its future success assured, and there is reason to hope that similar success and usefulness will attend such an association in Great Britain, where, in proportion to population, there are more medical libraries than in the United States, or perhaps any country in the world. As long ago as 1836 THE LANCET drew attention to the regulations which then restricted the usefulness of the many valuable books contained in our medical libraries. It was in reviewing the "Manual of Select Medical Bibliography" by J. Forbes, M.D., F.R.S., and in glancing over the long list of valuable works registered by Dr. Forbes that we were impelled to lament the exclusion of the medical profession from the advantages of resort to their pages, and to regret the neglect of medical bibliography in England. We have the authority of Mr. Barlow for stating that many of our observations made in 1836 in regard to medical bibliography are applicable at the present time. Our object is to draw attention to the sorry state of medical bibliography in this country and the endeavours which are being made to remedy it. Therefore, we heartily commend the suggestions of Mr. Barlow—namely, that in the first place printed catalogues of the principal medical libraries of London are necessary in order that one library may know what another contains; and secondly, that each library should possess a catalogue of its own deficiencies in relation to the collective resources of the rest. A system of coöperation is needed whereby facilities for reference may be increased by the exchange of duplicates and the loan of books by one library to another. The work of preparing such a catalogue and organising coöperation might well fall within the scope of the Medical Library Association; and younger libraries, say those in course of formation in our colonies, would benefit by systematic stocktaking in this country, for to them all the surplus could be offered on generous terms.

THE SOCIETY OF APOTHECARIES.

THE Master (Mr. A. T. Norton) and Wardens (Mr. Arthur Long and Mr. Bramley Taylor) of the Worshipful Society of Apothecaries entertained a large company at dinner in the hall of the society on Nov. 22nd, the chief guests of the evening being the new Lord Mayor and Sheriffs. Amongst those supporting the chair were Sir Thomas Barlow, Sir Henry Morris, Sir David McVail, Sir F. H. Champneys, Sir Thomas Fraser, and Dr. Norman Moore. After the loyal toasts had been given and responded to, the Worshipful Master, in proposing that of "The Lord Mayor, Sheriffs, and Corporation of the City of London," pleaded for a State university, and said he thought that the present standard of the London University in regard to medical qualifications was too high. The Lord Mayor, in responding to this toast, referred to the advantages of the apprenticeship system, and thought it was doubtful whether funds would ever be available which would be sufficient to establish a State university. He disagreed with the Worshipful Master as to the standard of the London University being too high. In the matter of medicine he thought it was most important to make the qualifications worthy of the great profession. Sir Thomas Barlow, in responding to the toast of "The Royal Colleges of Physicians and Surgeons," proposed by the Senior Warden, refuted the view that the College of Physicians was a *passé* institution or an oligarchy, and pointed out the important work which the College did in the interests of its members and of the community. Their relations with the Society of Apothecaries were cordial, and he hoped to see the society more closely associated with the Colleges. Sir Henry Morris followed in a

similar vein, remarking that the Colleges, amongst other good work, endowed and financed research. The Lord Mayor, in proposing "The Health of the Worshipful Master," gave a brief history of the society, and he recounted the interesting fact that in its early days the society included in its livery grocers, who, however, objected to associating their business with drugs, and so they founded a company of their own. His lordship thought that much good could be done now if the business in drugs could be entirely dissociated from the grocer. The Worshipful Master replying, referred to the excellent laboratory of the society, in which drugs were chemically and physiologically standardised, adding that this work was far beyond British Pharmacopœia requirements. They hoped soon in regard to medicaments to throw off empiricism and to begin seriously to develop the mathematics of drugs. After the toast of "The Visitors" the company dispersed. The occasion was a most enjoyable one, the dinner was excellently served, and the choice of music and the rendering of it were in very good taste.

MEDICAL ORGANISATION IN SOUTH AFRICA.

WE took occasion, a couple of months since, to refer to this subject,[1] and are now glad to record the useful work that is being carried out by the official bodies charged with the supervision of matters concerning the medical profession in the several provinces. One of the most important of these from the point of view of the general public, quite as much as from that of the medical profession, is irregular practice by unqualified persons. In unsettled countries and communities on the borders of civilisation this is unavoidable: every pioneer and explorer should have some knowledge of medicine and surgery, in the first place for his own sake, and next, for the good of his neighbours and dependents. But as civilisation advances, the rough-and-ready, though in their proper place invaluable, methods of the untrained, and therefore "unqualified" practitioner, must give way. In Natal there appear to be native "medicine-men," licensed under the Native Code to practise amongst natives, but who also carry on practice amongst Europeans. The Natal Medical Council, in dealing with such a case, came to the conclusion in September last[2] that the only course to pursue would be to abolish entirely the granting of licences to these "medicine-men." Their knowledge is rudimentary and erroneous, and their methods are barbarous and superstitious, also quite inadequate, and often harmful. The mere fact of their holding licences implies the approval by Government of such practices, and retards progress in the native population generally, confirming them in their ignorance. Moreover, in no other province in South Africa are native medicine-men licensed by Government. We trust the Union Administration will endorse this view, but at the same time they must deal fairly with those who have been, so far, encouraged by the State. The alleged "covering" of an unqualified person was inquired into at the September meeting of the Medical Council of Cape Colony, together with such matters as non-notification of infectious disease and contravention of the Medical and Pharmacy Act, and the requisite action was taken. The Orange River Medical and Pharmacy Council dealt with the prevalence of syphilis amongst natives, and the conduct of the examination for licensing chemists and druggists. The discussion of such matters at monthly meetings of representative members of the profession possessing official status is a means of focussing expert knowledge and directly influencing administrative action that appears to be particularly valuable.

REPRESENTATION OF THE UNIVERSITY OF LONDON IN PARLIAMENT.

WE are informed that Sir Victor Horsley will stand in the Election immediately at hand as a candidate for the representation of the University of London. At a recent meeting of the executive of the Liberal Association Sir Victor Horsley was selected for nomination to a meeting of the association to be held on Monday next. We understand that he is being supported by a large number of graduates.

THE ETIOLOGY OF PSORIASIS.

FOR many years the cause of psoriasis has been a keenly debated subject amongst dermatologists. While many have inclined to the nervous theory of its origin and others have supported the idea that it is associated somehow with gout and rheumatism, there have always been a few who have been inclined to ascribe it to the action of a micro-organism. Lang in 1878 described a fungus, but few accepted it, and it is generally discredited now. From time to time other observers have seen cocci and bacilli in the lesions, but for the most part, if not entirely, these have been accidental contaminations. Yet the facts supporting the idea of a microbic origin of the disease have appeared so potent that many dermatologists have searched for some organism as the true cause of the disease. To the present issue of THE LANCET Dr. A. D. Serrell Cooke communicates a brief note on some researches which he has recently been making. He has investigated 20 cases of psoriasis and amongst many organisms present he has discovered a short thick bacillus in all the cases of the disease examined. It appears to have well-marked characteristics, and he is pursuing his investigations especially with regard to the question of the communicability of the disease and the effect of vaccine treatment. We look forward with interest to a fuller account of his investigations, and meanwhile judgment must be suspended as to the accuracy of his conclusions.

A WORKING PLAN OF CLINICAL MEDICAL TEACHING.

WE have received a pamphlet with the above title which is a reprint of an article published in the *Edinburgh Medical Journal* for October by Dr. William Russell. It describes the arrangements made in his wards for the clinical instruction of women students, for which purpose they are set apart. A plan has been mapped out so that the students attend for clinical instruction in medicine for two winter and for two or three summer sessions. The first class is taken during the summer session following the third winter, by which time the students have passed their examinations in anatomy and physiology and have attended a course of lectures on pathology. In this class, which meets three times a week, the instruction consists in observation, in the education of the senses for purposes of clinical examination, and in a study of the normal and of simple abnormal physical signs. Especial attention is given to practice in percussion and auscultation. In addition, two clinical lectures a week are given to this class, and they are occupied in the explanation of the phenomena observed in the practical class. Dr. Russell regards this elementary class as of such importance that he takes it himself and does not delegate it to an assistant. During the fourth winter session the students attend lectures on systematic medicine and work in the wards at case-taking. A clinic is held on three days a week, when selected cases are read, examined, and discussed. On two days a week a clinical

lecture is given on a case or group of cases or on some special subject. Fifth-winter students also attend these lectures, and in addition they have special clinics on one or two days. Senior students in their final summer term attend in the wards on three days a week for more advanced clinical teaching, and Dr. Russell suggests that if his plan were generally adopted, this term might with advantage be devoted to special subjects rather than to attendance in the general medical wards. Dr. Russell's scheme has the merits of being practical and of devoting sufficient attention to a subject which is often far from systematically taught. We are in full accord with his contentions that the first instruction in the observation and record of physical signs should be given by some one of considerable experience in teaching, and that normal, as well as abnormal, signs should be thoroughly mastered by the student. There can be no doubt that if some plan such as he outlines were generally adopted the subject of clinical medicine would prove more attractive to the student and would be more thoroughly taught than is often the case at present.

A NEW HUMAN TRYPANOSOME FROM RHODESIA.

WHILE examining the blood of a rat which had been artificially infected from a patient under treatment for sleeping sickness in the Royal Southern Hospital at Liverpool Dr. J. W. W. Stephens discovered that the trypanosome present in the rat showed certain peculiar features. These were investigated by him in association with Mr. H. D. Fantham and the result of their researches was communicated to the Royal Society at a recent meeting. A short *résumé* of the paper also appears in the current Twenty-first Bulletin of the Sleeping Sickness Bureau. The patient from whom the rat was inoculated was a European who had contracted sleeping sickness in North Eastern Rhodesia, where it may be mentioned the recognised transmitter of the disease, the glossina palpalis, has not been found. The case was also noteworthy inasmuch as it was in this patient that Major Ronald Ross and Dr. David Thomson demonstrated a regular periodical increase of the parasites, an account of which observation was published in the Nineteenth Bulletin of the Sleeping Sickness Bureau. The peculiar morphological forms of this trypanosome were not seen in the blood of the patient, in whom, however, trypanosomes were always very scanty, but they were observed in laboratory animals, including certain monkeys, rabbits, and guinea-pigs, as well as rats. The main peculiarity of the new trypanosome, to which attention is drawn, is that among the short or stumpy forms some have the nucleus at the posterior (non-flagellar) end. There are all transitions between forms in which the nucleus is in the middle to forms in which it is actually terminal and posterior to the blepharoplast (kinetonucleus). In rats infected with this strain a few long trypanosomes appear in the blood in about three days, while the stumpy forms with the nucleus posterior are seen about the fifth or sixth day. Many of the long forms have an elongated posterior end or snout; the strain could be distinguished by this feature. It was noted that pear-shaped or rounded forms with little or no flagellum are not uncommon in this Rhodesian strain. It is stated that the posterior nuclear forms were seen in rats infected from the patient before he was treated with drugs. It appears that the strain is somewhat more virulent in rats and guinea-pigs than the old laboratory strain of T. gambiense, and it is, moreover, resistant to atoxyl. The writers in their paper discuss two views: 1. The trypanosome described is a variety or "local race" of T. gambiense, due perhaps to some change of environment, and possibly associated with its transmission being effected by some species of glossina other than G. palpalis. The idea that it is merely a laboratory variation is rejected, since all known laboratory strains of T. gambiense are practically identical in morphology. 2. It is really a new species of trypanosome which produces sleeping sickness in man; this is the conclusion to which the writers incline, since the Rhodesian trypanosome differs from T. gambiense more than, for example, T. brucei does from T. evansi. Also the T. gambiense is believed to be transmitted solely by G. palpalis, which does not, however, exist in North Eastern Rhodesia; but even if it did there is still great probability that the parasite in question is a new species. The writers therefore propose to regard it as a new human trypanosome and to name it T. rhodesiense.

PUBLIC HEALTH IN CEYLON.

Sir Allan Perry, principal civil medical officer and inspector-general of hospitals, presents a report on Ceylon hospitals for 1909, which, he considers, shows some improvement over the previous year. The estimated population of the island was 4,082,935; the birth-rate, 36·7 per 1000, showed a decrease, and the death-rate, 30·3, showed a slight increase on the figures for 1908. On the whole the health statistics showed an improvement on the previous year; malarial fever was less, small-pox and cholera much less. Malaria does not occupy the important place in the vital statistics of Ceylon that it does in many provinces of India: the total number of cases treated in hospitals and dispensaries numbered 512,855; the deaths in hospitals numbered 612, and the total deaths registered as due to this cause 852. Efforts are being made to instruct the population in simple measures of fever prevention, and it may be hoped that the lectures to school teachers and others will in time lead to good results. Some improvement has already taken place in the sanitation of small towns, in the way of draining and filling up pools; but no large works have been undertaken, and Sir Allan Perry regrets that the suggestion for the formation of mosquito brigades has not been adopted. He considers that legislation is necessary to compel public bodies to take action, in carrying out "the ordinary simple means by which" malaria may be eradicated. The large majority of the people are apathetic; we presume this is due to ignorance, such as has been successfully overcome in many parts of India. Quinine is distributed free, and has been of marked benefit in places. A "spleen census" was taken towards the end of the year, 317,694 children under 15 years being examined; 20·81 per cent. were found to have spleens more or less enlarged; in 1908 the percentage was 34·05. Small-pox prevailed but slightly, only 62 deaths having occurred; 46 of these were in the Colombo Infectious Hospital, all among unvaccinated persons. Ankylostomiasis is showing a tendency to spread in the island; it is found chiefly among the South Indian coolies imported as estate labourers, and from them spreads among the indigenous population in the villages in the neighbourhood of the estates. 4896 cases were treated in hospital (compared with 4434 in 1908); the deaths numbered 1184. There is an immigration depôt at Ragama; during the year the dejecta of 864 arrivals from India were examined microscopically, and in 417 cases—i.e., 48 per cent. of the new arrivals—the ova of the parasite were detected. The disease being widespread on the neighbouring continent, the daily importation of infection carriers, the continued pollution of soil and water on estates, and the lack of efficient sanitary precautions against its spread, are subjects for grave consideration. On one group of estates it is noted that 568 persons out of a total labour force of 1416 were suffering from the disease. Unless stringent measures are taken it will spread throughout the colony. A Government despatch was

issued in February, 1909, pointing out the lines on which preventive measures should be taken; beta naphthol is the anthelmintic considered to be the most suitable for general use. In regard to general sanitation, the principal medical officer does not consider the state of Ceylon to be satisfactory; only in towns having municipalities and local boards is any attempt at sanitation made; in other places there are neither drains, refuse disposal, nor water-supply. In Colombo the water-supply is not sufficient, and an increase must shortly be provided. Good progress is, however, being made with the sewerage works designed by Mr. Mansergh. The health statistics of the Colombo municipality were favourable in 1909, the death-rate, 33·5 per 1000, being appreciably less than in 1908 (36·7), and slightly less than the decennial average (34·3). There was diminution in the mortality from diarrhœal diseases and fevers, and in the infantile mortality. On the other hand, pulmonary diseases caused the highest death-rate yet recorded (4·33). In regard to general measures of sanitation, such as provision of a pure drinking water (which is derived from an excellent source in the hills, 25 miles distant), supervision of milk and food-supplies, &c., the health officer, Dr. W. Marshall Philip, has the same difficulties to face as at home, but in a heightened degree; he has been successful in producing decided improvement. Milk adulteration appears to be practised extensively, one dairy alone having furnished 49 adulterated samples out of 66 taken for examination. A very large quantity of tinned milk is used for infant feeding, even amongst the native races, which is much to be regretted.

AT the meeting of the Medical Society of London to be held at 11, Chandos-street, Cavendish-square, W., on Monday, Nov. 28th, at 8.30 P.M., Dr. F. J. Goodhart will introduce a discussion on Dilatation of the Heart and Heart Strain. Sir R. Douglas Powell, Sir Lauder Brunton, Dr. Samuel West, Dr. W. Collier (Oxford), and Dr. Henry Davy (Exeter) have promised to take part in the discussion.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

Concerning the Running of the 14-16 Darracq.

SINCE writing about this cheap and, I believe, reliable car, I have had a good many inquiries from medical men as to the suitability of these automobiles for professional use. Probably the following letter which I have received from Dr. W. W. Stainthorpe of Guisborough, Yorkshire, may be of interest to any thinking of buying one of these cars. Dr. Stainthorpe writes:—

It is no trouble to send you particulars of my 14-16 Darracq, of which I cannot speak too highly. I may tell you that for four years I ran an 8-h.p. De Dion without any trouble to speak of, so you will understand how careful I would be before putting into writing my experience of another make of car, as I consider that car one of the best of its size. Well, reverting to my original text, the following items may interest you and assist others to weigh in the balance my experience, should they anticipate the purchase of a 14-16 Darracq. I have now run my car 3150 miles upon all kinds of roads and by-lanes, in all weathers, night and day, without any involuntary stop. In doing so it has consumed 132 gallons of petrol (the miles per gallon would have been greater had I not used the car in the town to make frequent calls), and 16 gallons of lubricating oil, including a small quantity left in the tank and emptied out at the end of every 1000 miles, when the engine is washed out, and fresh oil put in. I have had two of the sparking plugs renewed, as they missed fire due to over-filling the oil tank, which caused them to become sooted, so that I still carry them as spares; the other two have not been touched. The front ungrooved Dunlops show little signs of wear; the two back grooved ones have just worn the grooves out, but should stand another 2000 miles. I have had two punctures from nails, the repairing of which cost 5*s*. No repairs to the car.

The Book of Bibendum.

The Michelin Tyre Company, Limited, of Sussex-place, London, have published a little book which deals with tyres, and which will be found of great assistance to all who use pneumatic tyres, for, as the author states on the first page,

> "He who to be an expert motorist aspires
> Must first learn all there is to know about his tyres."

Those who have not already a copy will be well advised to apply to the Michelin Company for one.

Loose Nuts, Bolts, and Pins.

No matter how carefully a car is put together, the constant vibration to which cars are subjected may occasionally cause the slackening or even the complete working out of some of these fastenings, with maybe serious consequences. It is well, therefore, to be constantly on the look-out for nuts that have worked loose or dropped out. Only recently I had a letter from a medical man who was put to the expense of a new crank and connecting-rod simply as a result of his not seeing that the split pin on one of the engine big bearings was in place. Constant inspections and trials with a spanner would in this case have saved a rather heavy repair bill. Another source of worry is overheating. A medical friend, who makes a great point of always keeping his car in perfect trim, recently had much trouble in this respect. The new aluminium paint with which he coated his engine would peel off, and, what was worse, the engine would get so hot that the mixture exploded prior to compression and there was great loss of power. The water-circulating pump worked well, neither ignition nor carburettor was at fault, and the compression was excellent, and yet the fault continued. By chance the cause was discovered. The back wheel brakes were operated by a cable, and the pins in the rocking piece had worn, with a result that occasionally, when the brakes were used, they did not disengage when the lever was brought back, and so the car was run with the brakes unknowingly on. The engine thus had an extra load and so became heated. Re-drilling the holes in the rocking piece and fitting new pins soon effected a remedy.

The Angle of the Steering Column.

Those who propose to be their own drivers should, when ordering a car, see that the angle of the steering column suits their height. I had a lesson recently which brought this fact forcibly home to me. A friend lately bought a landaulette with the idea of occasionally driving himself, and knowing my interest in motoring kindly asked me to drive the car home for him. The car was an excellent little landaulette, but the steering pillar was almost vertical, and as a result it was not quite a joy driving the car some 80 miles. In order to allow of more room in the rear the driving seat was brought forward, and thus the steering column was almost vertical. It permitted of a roomy body at the back, but it was the reverse of comfortable for the driver.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE twenty-sixth annual meeting of the Fellows and Members of the Royal College of Surgeons of England was held on Nov. 17th.

Mr. BUTLIN, the President, was in the chair, and he commenced the proceedings by saying that he thought it would interest them to know that 3600 copies of the annual report of the Council had been supplied to Fellows and Members. He then laid the report before the meeting and proceeded to speak on several of the items contained in it. He referred at first to the resolutions carried at the last annual meeting, and explained that though it had been customary to send answers to the resolutions carried to the mover and seconder of each resolution, on this occasion the Council had departed from that practice. With regard to the second resolution which related to the necessity for amending the Midwives Act, he would refer the meeting to page 5 of the present report, in which there was printed a letter written by himself to the Privy Council pointing out the importance of the need for an amending Act, and urging that the onus of obtaining the fee should not be thrown upon the medical man. The reply received from the Privy Council was also to be found in the report. All were agreed that provision must be made for enabling the medical man to recover his fee, but great difference of opinion seemed to exist as to the most suitable public body for enforcing the fee. The amending Act made the boards of guardians responsible for the remuneration of medical men summoned on the advice of the midwife, but it was the opinion

of a large body of practitioners that the responsibility should be cast upon the local supervising authorities. With regard to the third resolution carried at the last annual meeting, which concerned the question of the union of the two Royal Colleges with the University of London, he referred them to page 10 of the present report, which contained an account of what had been done by the two Royal Colleges. As a commission was sitting to consider the question nothing more could at present be done. With regard to the first resolution, which urged the importance of the representation of Members on the Council, a special committee of the Council had been appointed; it thoroughly considered the matter and had reported to the Council against the suggested alteration, and the Council therefore had decided to take no steps in regard to the representation of Members on the Council. The question of the administration of anæsthetics had recently excited much attention, for with the law as it stood at present anyone might administer anæsthetics, and not long ago the College had been asked to take action in a case where a firm of dentists had employed their servant-maid as anæsthetist, but unfortunately the reply had to be given that in the present state of the law no one could interfere in the matter. Even the question of local anæsthetics was of great importance, especially since the introduction of spinal anæsthesia, which might be called a form of local anæsthesia. The matter was of great importance and some legislative action must be taken. He would next refer to the awarding of the honorary medal of the College; this had been given to Dr. Robert Fletcher of Washington in recognition of his valuable work in connexion with the index catalogue of the library of the Surgeon-General's Office, Washington. Dr. Fletcher was a Member of the College, and was a native of Bristol, though he had lived many years in the United States. He was pleased to be able to announce that the King, who had been made an honorary Fellow while he was Prince of Wales, had acceded to the request that he should continue to be an honorary Fellow of the College. The erection of the new Examination Hall would shortly begin, and a few days ago the College had accepted a tender for the building. In connexion with the Museum he would like to point out that the odontological collection of the Royal Society of Medicine had been entrusted to the College, and it had been fitted up there at some little expense. The College only acted as the guardians of the collection, but if at any time the Royal Society of Medicine decided to resume possession of it all the capital expenses of the College would have to be repaid. The collection was probably the finest odontological collection in the world, and he invited the Fellows and Members present to view it after the meeting. He would also refer to two other exhibits in the Museum; one was a mummy which was in possession of the College, which had been examined by Professor G. Elliot Smith, and as the result of his examination it seemed to be clear that this was the oldest mummy known in the world by at least a thousand years. Another item of importance was a cranium which was presented to the College by Mr. George Busk in 1868, and as it had come from Gibraltar it was generally known as the Gibraltar skull. This was perhaps the oldest known human skull, probably older than the Neanderthal skull.

The PRESIDENT then invited any questions in connexion with the Report.

Dr. S. C. LAWRENCE inquired how many women had been admitted Members of the College; the answer was "One." Inquiry was also made as to the obituary list of Members printed in the report, and it was explained that it could not be said they had all died during the past academical year, for occasionally some months elapsed after the death of the Member before it was known to the College.

Mr. DENNIS VINRACE expressed the hope that in future reports more details would be given as to the items of expenditure, for he found salaries and wages were grouped together and no information was given as to the separate items.

The PRESIDENT promised to consider the matter.

Mr. VINRACE further inquired as to the custom with regard to the removal of Members from the roll; he wished to know whether the Council accepted the decision of the General Medical Council, or whether it inquired into each case for itself? In reply, the PRESIDENT said that they inquired most carefully into every case and decided on its own merits, and occasionally it happened that though the name of a Member had been removed by the General Medical Council the Council of the Royal College of Surgeons had retained it on the Roll of Members.

In reply to a question as to the possibility of the restoration of any Member who had been removed, the PRESIDENT explained that they were always ready to consider applications for restoration, and sometimes they found themselves able to restore the names of former Members.

The President was then asked whether he was aware that some county councils were requiring the midwives who called in medical men to their assistance to report on the time of attendance of the medical man and to express an opinion as to the manner in which he did his work. The PRESIDENT replied that he was not aware of this, and he agreed that such a condition of affairs could not be allowed to continue.

No more questions being put, the PRESIDENT called upon Mr. JOSEPH SMITH to propose the motion standing in his name. It was as follows:—

That this twenty-sixth annual meeting of the Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council, which as now constituted does not represent the whole corporation, and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

Mr. Smith said that for 25 years he had brought forward resolutions of the same purpose as this. He had been asked what the resolution meant, and he would simply say that it claimed for the 15,000 Members of the College some right in the management of its affairs. At present they were utterly ignored. The condition of affairs was an absolute anomaly at the present day, and it must come to an end sooner or later. He appealed once more to the Council to grant to the large body of Members some representation on the Council.

Dr. LAWRENCE seconded the motion, and pointed out that in many respects the actions of the Council were not in accord with the wishes of the Members. Although the Council had taken the vote of the Members as to the desirability of admitting women to the examinations of the College, and although the majority of the Members had voted against it, yet the Council had disregarded the opinion of the Members and had admitted women to examination. With what result? That only one woman Member had been admitted. By the charter of 1800 the property of the College was vested in the Members and nothing could deprive them of their rights. If the Council persisted in its present attitude the Association of Members would adopt a more militant course.

Mr. F. W. COLLINGWOOD supported the motion and complained that the present constitution of the College was mediæval in character. The principal of representation was to be seen everywhere at the present day and in this College only was it absent. He asked the Council for the reasons why Members should not have some control of the affairs of the College.

Sir VICTOR HORSLEY asked the President to let the meeting have the report of the committee of the Council on the question of the representation of Members.

The PRESIDENT stated, in reply, that in the annual report for 1907 were to be found all the reasons *pro* and *con.* in connexion with the question of the representation of Members.

Sir VICTOR HORSLEY pointed out that he was not asking for this report of 1907, but for the report presented to the Council by its own committee this year.

The PRESIDENT said that all the arguments were contained in the report he had mentioned.

Sir HENRY MORRIS explained that though the whole subject of the representation of the Members was considered, the chief matter before the committee was the question whether any new arguments had arisen either in favour of or against the representation of the Members, and the committee had had to reply that no fresh matter had been brought forward.

In reply to a Member asking whether the reference to the committee of the Council had been limited in any way, the PRESIDENT denied that there had been any limitation, and stated that the mode of considering the question had been left to the committee.

Dr. W. G. DICKINSON read an extract from a speech by the President on behalf of the direct representation of medical

men on the General Medical Council, and he claimed that all the arguments brought forward in that speech applied with equal force to the claims of the Members of the Royal College of Surgeons to representation on the Council.

A Member urged that a deputation should wait upon the Council to discuss the matter, and Mr. J. BRINDLEY JAMES seconded the suggestion.

The PRESIDENT then put Mr. Smith's motion to the meeting. A large number of those present voted in its favour and none voted against it, and the President declared the motion carried.

With a vote of thanks to the President for taking the chair at the meeting the proceedings came to an end.

SANITATION IN INDIA.

(*Concluded from p. 1513.*)

Lunatic Asylums.

THE report on lunatic asylums under the Government of Bombay for 1909, rendered by Surgeon-General H. W. Stevenson, I.M.S., refers to the condition of 1355 lunatics, of whom 339 had been admitted during the year; the daily average strength was 988·6, a higher figure than in the two previous years; the daily sick-rate was 23·9 per 1000. The condition of the asylums is stated to be one of steady, though not very rapid, improvement; a good deal has been done towards the betterment of the buildings, but there is great need for a higher and more intelligent class of men and women for attendants. Cholera broke out in two asylums, Naupada and Poona; at the former place there were 41 attacks and 34 deaths. Major S. Evans considered that the infection was most probably brought into the asylums by means of vegetables from the kitchen garden. There are few instances of disease outbreaks proved to be due to vegetables or fruit infected by the application of human excreta to the soil as a manurial enrichment, and it is entirely wrong to apply such excreta to soil growing fruit or vegetables that may be eaten raw. It is to be hoped that proper supervision will be henceforth exercised so as to prevent such an obviously dangerous and filthy proceeding in a state institution under European medical control. At the Poona Asylum 5 cases of cholera occurred in July with 3 deaths; they were sporadic cases, and no cause appears to have been detected. Of the admissions 32·7 per cent. were discharged cured and 35·7 per cent. died.

In Bengal the total asylum population amounted to 1062, of whom 178 had been admitted during the year; the daily average strength was 886·5, an increase on the three previous years. The daily sick-rate was 115·7, a slight increase on the two previous years; but the death-rate, 5·3 per cent. of strength, was very low; 35·2 per cent. of the admissions were discharged cured and 24 per cent. died.

In Eastern Bengal and Assam the total asylum population was 651, of whom 153 had been admitted during the year. The daily average strength was 510·6, an increase on the two previous years, and the daily average sick-rate was 34. The death-rate was high, 13·5 per cent. of strength, the chief items being bowel complaints and tubercle. One death, mentioned by Colonel R. N. Campbell, Inspector-General of Hospitals, was of very unusual occurrence—viz., suffocation from the presence of a round worm in the larynx. A curious manner of escape from the asylum was devised by a female criminal lunatic—namely, through the hole below the seat of a latrine, which she managed to widen. Of the cases admitted 25·4 per cent. were discharged cured and 41·8 per cent. died.

Colonel T. Bate reports that the Punjab asylum at Lahore has been enlarged. This improvement affords relief from overcrowding and facilitates classification of patients; it also includes special provision for the isolation of tubercle cases, which is very necessary on account of the peculiar liability of the insane to contract this disease. The total asylum population (for the province) amounted to 837, of whom 188 had been admitted during the year; the daily average strength was 632·8. The daily average sick-rate was 75, an increase on the two previous years; 48·2 per cent. of the total admissions were cured and 42·7 per cent. died.

The Surgeon-General with the Madras Government reports that the population of the asylums is steadily increasing, there having been an advance of 24 per cent. since 1900; the increase in females has been double that in males. The total asylum population in 1909 has been 881, of whom 203 were admitted during the year. The daily average strength was 677. The average sick numbered 67·86, an increase on the two previous years; 39·6 per cent. of the admissions were cured and 21·1 per cent. died.

In all these Indian asylums the majority of cases were of maniacal insanity, the proportion varying from 50·8 in Bombay to 63 per cent. in Eastern Bengal. The melancholic cases varied between 7·7 per cent. in Madras and 27 per cent. in Bombay.

Vaccination.

The reports on vaccination for the three Presidency provinces have not yet come to hand: in the remaining six provinces the results may be considered satisfactory, bearing in mind the difficulties that have to be contended with—amongst them the "conscientious objector" has not yet to be included. Nearly the whole of the work is done by the vaccination department; in addition some is carried out by the staff of the dispensaries. The percentage of success obtained on primary vaccination was always high, varying from 95·27 in Burma to 99·23 in the Central Provinces. (The case success with the Local Government Board's glycerinated calf-lymph in 1909 was 99·4 per cent.) On revaccination the successful percentage varied between 61·58 in Burma and 82·76 in the North-West Frontier Province. The proportion of persons per 1000 of the population that are successfully vaccinated varies between 28·30 in the United Provinces and 47·36 in the North-West Frontier Province, where the number vaccinated showed an increase of 20·82 per cent. over the previous year. It is stated that many trans-frontier people brought their children to be vaccinated, and that many petitions for the services of the Government vaccinator were received. When it is remembered that this province was only constituted ten years ago, and that the inhabitants are wild and warlike tribes only just entering on civilisation, great credit must be given to the local medical administration for bringing about such a satisfactory state of things. Glycerinated calf-lymph is used universally, being in all cases prepared under Government supervision. In the United Provinces there was a falling-off in vaccination, owing to the great prevalence of malaria, with heavy infant mortality, the majority of the surviving children being also in an unfit condition to be vaccinated. Lieutenant-Colonel J. C. Robertson, I.M.S., Sanitary Commissioner, mentions that thermos flasks had been used for packing lymph tubes during the hot weather, but they had to be discarded owing to breakages. In the Punjab vaccination was carried out under difficulties, owing to the ravages of plague. In the Central Provinces also a considerable falling-off in vaccination is reported, due to the low birth-rate and the presence of plague.

Chemical Examinations.

The reports of the chemical examiners for Bombay, Bengal, the United Provinces, Central Provinces, and North-West Frontier Province indicate that a large amount of work is done of a necessary character; partly medico-legal (cases of suspected poisoning, human and animal), partly of water samples, and partly of revenue articles, such as wine, spirits, and petroleum. In the Bengal laboratory 2405 medico-legal cases were investigated in 1909, 775 being examinations of human viscera for the presence of suspected poison, mostly opium; poison was detected in 310 instances. In the United Provinces Dr. E. H. Hankin investigated 1448 medico-legal cases, the total number of articles analysed being 2938; he also examined and reported on 2072 samples bacteriologically, most of them being samples of water; "microbes having the character of cholera vibrios" were detected in 17 specimens of water; in no case was a microbe resembling enteric detected. B. coli communis was found in 9 out of 145 water specimens. With such an immense amount of routine work to get through it is obvious that these officers have little leisure for any original research, either chemical or bacteriological, however well they may be aided by intelligent subordinates. The Bengal examiner does not appear to have dealt with bacteriology during the past year, but the range of his investigations (in addition to water analysis and medico-legal matters) extended from the examination of milk and tinned meats to "the reasons for certain percussion-caps hanging fire," and "whether a specimen of fluid can be described as eau-de-cologne"; and the number of analyses performed reached a total of 6646. At one

time the Agra laboratory was the source from which emanated many original ideas and practical improvements in chemical and bacteriological methods. Possibly official annual reports are not the medium chosen by which to communicate scientific work to the outside world.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 7700 births and 5040 deaths were registered during the week ending Nov. 19th. The annual rate of mortality in these towns, which had increased from 13·0 to 14·8 per 1000 in the four preceding weeks, further rose to 15·5 in the week under notice. During the first seven weeks of the current quarter the death-rate in these towns averaged 13·6 per 1000. In London the death-rate during the same period, calculated on the probably over-estimated population, was equal to 13·7 per 1000. Among the 77 towns the death-rates last week ranged from 6·2 in Reading and in King's Norton, 6·3 in Hornsey, 7·4 in Walthamstow, and 7·7 in East Ham, to 20·6 in Aston Manor, 21·8 in Grimsby, 21·9 in Middlesbrough, and 22·3 in Burnley. The 5040 deaths from all causes registered in the 77 towns last week showed an increase of 239 upon the number in the previous week, and included 403 which were referred to the principal epidemic diseases, against 424, 361, and 392 in the three preceding weeks; of these 403 deaths, 164 resulted from measles, 75 from diarrhœa, 55 from diphtheria, 55 from whooping-cough, 33 from scarlet fever, and 21 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·2 per 1000, against 1·3, 1·1, and 1·2 in the three preceding weeks. No death from any of these diseases was registered last week in Croydon, Derby, Southampton, Norwich, or in 12 other smaller towns; the annual rates therefrom ranged upwards to 2·6 in Coventry, 2·8 in Brighton and in Burton-on-Trent, 3·1 in Rotherham, and 5·0 in Plymouth. The fatal cases of measles in the 77 towns, which had been 107, 101, and 136 in the three preceding weeks, further rose to 164 last week, and exceeded the number in any week of the current year; they caused the highest annual death-rates of 1·4 in Portsmouth and in Grimsby, 1·6 in Rotherham, 1·8 in Tynemouth, 2·4 in Brighton, and 4·1 in Plymouth. The deaths attributed to diarrhœa, which had declined in the 11 preceding weeks from 527 to 110, further fell last week to 75, and included 23 in London, 5 in Sheffield, 4 in Birmingham, and 3 in Liverpool and in Manchester. The deaths referred to diphtheria, which had steadily increased from 34 to 54 in the five preceding weeks, were 55 last week, and were proportionately most fatal in Bolton, Barrow-in-Furness, and Burton-on-Trent. The 55 fatal cases of whooping-cough exceeded by 18 the low number in the previous week; 7 were registered in London, 5 in Liverpool, and 5 in Manchester. The deaths referred to scarlet fever, which had been 30 and 23 in the two preceding weeks, rose last week to 33, of which 8 occurred in London, 6 in Liverpool, and 3 in Smethwick. The 21 fatal cases of enteric fever showed a decline of 11 from the number in the previous week, and included 4 in London, 3 in Manchester, and 2 in Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily increased in the 13 preceding weeks from 1428 to 1882, had declined to 1843 on Saturday last; 180 new cases of this disease were admitted to these hospitals during last week, against 188 and 239 in the two previous weeks. The 1537 deaths from all causes in London last week included 396 which were referred to pneumonia and other diseases of the respiratory system, against 234, 246, and 319 in the three preceding weeks, and exceeded by 82 the corrected average number in the corresponding week of the five years 1905–09. The causes of 39, or 0·8 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 54 other smaller towns; the 39 uncertified causes of death in the 77 towns last week included 8 in Birmingham, 6 in Liverpool, and 4 in Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 779 births and 588 deaths were registered during the week ending Nov. 19th. The annual rate of mortality in these towns, which had been equal to 13·6 and 13·3 per 1000 in the two preceding weeks, rose to 16·2 in the week under notice. During the first seven weeks of the current quarter the death-rate in these eight towns averaged 13·7 per 1000, and was 0·1 per 1000 above the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 9·8 and 12·6 in Perth and Leith, to 19·5 in Paisley and 21·3 in Greenock. The 588 deaths from all causes in the eight towns last week showed an increase of 104 upon the number in the previous week, and included 61 which were referred to the principal epidemic diseases, against 56 and 47 in the two preceding weeks; of these 61 deaths, 24 resulted from diarrhœa, 13 from whooping-cough, 8 from diphtheria, 7 from "fever," 5 from scarlet fever, and 4 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·7 per 1000, and was 0·5 per 1000 above the rate from the same diseases in the 77 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had declined in the seven preceding weeks from 51 to 17, were 21 last week, and included 10 in Glasgow and 5 in Edinburgh. The fatal cases of whooping-cough, which had been 7 in each of the two preceding weeks, rose to 13 last week, and of these 12 were registered in Glasgow. The 8 deaths from diphtheria showed a decline from the numbers in the two preceding weeks, and included 6 in Glasgow. The 7 fatal cases of "fever" showed an increase upon the numbers in recent weeks; of these 5, including 1 from cerebro-spinal meningitis, were registered in Glasgow and 2 in Edinburgh. Of the 5 deaths from scarlet fever, 3 were recorded in Glasgow and 2 in Edinburgh. The 4 fatal cases of measles occurred in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 84 and 65 in the two preceding weeks, rose to 121 last week, but were 74 below the number in the corresponding week of last year. The causes of 28, or 4·8 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 541 births and 396 deaths were registered during the week ending Nov. 19th. The mean annual rate of mortality in these towns, which had been equal to 16·8, 15·1, and 16·2 per 1000 in the three preceding weeks, rose to 17·9 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these Irish towns averaged 16·6 per 1000; the mean rate during the same period did not exceed 13·6 in the 77 largest English towns or 13·7 in the eight Scotch towns. The annual death-rate during last week was equal to 20·3 in Dublin, 17·6 in Belfast, 14·4 in Cork, 18·0 in Londonderry, 5·5 in Limerick, and 25·3 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 16·7 per 1000. The 396 deaths from all causes in the 22 town districts last week showed an increase of 38 upon the number in the previous week, and included 18 which were referred to the principal epidemic diseases, against 33, 28, and 27 in the three preceding weeks; these 18 deaths were equal to an annual rate of 0·8 per 1000, or 0·4 below the rate from the same diseases last week in the 77 towns, the rate in the eight Scotch towns being 1·7. The 18 deaths from these epidemic diseases in the Irish towns last week included 6 from diarrhœa, 4 from diphtheria, 3 from scarlet fever, 3 from whooping-cough, 1 from measles, and 1 from enteric fever, but not one from small-pox. The deaths attributed to diarrhœa, which had been 14 and 11 in the two preceding weeks, further declined to 6 last week, of which 3 occurred in Belfast and 2 in Dublin. Of the 4 fatal cases of diphtheria 3 were registered in Dublin and 1 in Belfast. Two of the 3 fatal cases of scarlet fever were recorded in Dublin

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING OCTOBER, 1910.

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

and 1 in Londonderry; and of the 3 deaths from whooping-cough 2 occurred in Dublin and 1 in Londonderry. The fatal case of measles was recorded in Dublin and that of enteric fever in Belfast. The deaths in the 22 towns last week included 80 which were referred to pneumonia and other diseases of the respiratory system, against 60 and 88 in the two preceding weeks. The causes of 9, or 2·3 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·8 per cent., while in the eight Scotch towns it was equal to 4·8 per cent.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1910.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from each of the nine diseases specified in the table was equal to an annual rate of 5·9 per 1000 of the population, estimated at 4,872,702 persons in the middle of the year. In the three preceding months the rates were 4·1, 3·9, and 5·3 per 1000 respectively. The lowest rates last month were recorded in Paddington, the City of Westminster, Hampstead, St. Marylebone, and Stoke Newington; and the highest rates in Finsbury, Bethnal Green, Poplar, Southwark, Bermondsey, and Battersea. Scarlet fever again showed a considerably increased prevalence last month; among the various metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, St. Pancras, Poplar, Lambeth, Battersea, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 1825 scarlet fever patients at the end of last month, against 1530, 1439, and 1630 at the end of the three preceding months; the weekly admissions averaged 229, against 190, 160, and 207 in the three preceding months. The prevalence of diphtheria also showed a further considerable increase last month; this disease was proportionally most prevalent in Chelsea, Islington, the City of London, Shoreditch, Southwark, Bermondsey, Lambeth, and Greenwich. There were 852 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 580 and 746 at the end of the two preceding months; the weekly admissions averaged 120, against 76 and 108 in the two preceding months. The number of enteric fever cases notified during the month showed a slight diminution from the exceptionally high number in the previous month; the greatest proportional prevalence of this disease was recorded in Hackney, Holborn, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Lewisham. The Metropolitan Asylums Hospitals contained 169 enteric fever patients at the end of last month, against 58 and 141 at the end of the two preceding months; the weekly admissions averaged 25, against 6, 11, and 32 in the three preceding months. Erysipelas was proportionally most prevalent last month in Hackney, Finsbury, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. The 25 cases of puerperal fever notified during the month included 4 in Paddington, 4 in Islington, 3 in Stepney, and 2 each in Fulham, Shoreditch, and Southwark. Of the 10 cases notified as cerebro-spinal meningitis 3 belonged to Islington and 2 to Fulham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the populations. During the four weeks ending Oct. 29th the deaths of 4496 London residents were registered, equal to a corrected annual rate of 12·6 per 1000; in the three preceding months the rates were 10·4, 10·3, and 11·9 per 1000 respectively. The death-rates last month ranged from 7·8 in Lewisham, 9·0 in Woolwich, 9·2 in Wandsworth, 9·4 in Fulham, 9·7 in Hampstead, and 9·9 in Stoke Newington to 16·2 in Poplar, 17·1 in Finsbury and in Southwark, 18·1 in Shoreditch, 19·1 in Bermondsey, and 20·1 in the City of London. The 4496 deaths from all causes included 466 which were referred to the principal infectious diseases; of these, 112 resulted from measles, 14 from scarlet fever, 33 from diphtheria, 31 from whooping-cough, 42 from enteric fever, and 234 from diarrhœa, but not any from small-pox, from typhus, or from ill-defined pyrexia. No death from any of these infectious diseases was recorded last month in the City of London; among the metropolitan boroughs the lowest rates from these diseases were recorded in Chelsea, Stoke Newington, Wandsworth, and Lewisham; and the highest rates in Hammersmith, Finsbury, Shoreditch, Southwark, and Bermondsey. The 112 deaths from measles were 64 in excess of the corrected average number in the corresponding period of the five years 1905–09; this disease was proportionally most fatal in Hammersmith, Islington, Finsbury, Southwark, and Bermondsey. The 14 deaths from scarlet fever showed a decline of 37 from the corrected average number; of these 14 deaths, 3 belonged to Lambeth, 2 to Islington, and 2 to Stepney. The 33 fatal cases of diphtheria were 15 fewer than the corrected average number, and included 7 in Southwark, 3 in Islington, 3 in Camberwell, and 2 each in Hammersmith, the City of Westminster, Wandsworth, and Deptford. The 31 deaths from whooping-cough showed a decline of 18 from the corrected average number; of these 31 deaths, 4 belonged to Bethnal Green, 3 to Hampstead, and 3 to Battersea. The 42 fatal cases of enteric fever were 11 in excess of the corrected average, and included 5 in Shoreditch, 5 in Bethnal Green, 4 in Hackney, 4 in Stepney, 4 in Lambeth, 3 in Islington, and 3 in Poplar. The 234 deaths from diarrhœa showed a decline of 43 from the corrected average number; the greatest proportional mortality from this cause was recorded in Paddington, Hammersmith, St. Pancras, Finsbury, Stepney, Southwark, Bermondsey, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 7·4 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeon: F. F. Mahon to the *Topaze*. Surgeons: R. M. Riggall to the *Vernon;* H. E. Perkins, S. W. Grimwade, B. Taylor, C. F. Willies, A. Scott, G. J. Carr, E. C. Holton, H. H. Ormsby, A. E. P. Cheeseman, J. G. Danson, and E. M. Browne have been entered in the Royal Navy as Acting Surgeons, and appointed to the *Victory*, additional, for course of instruction at Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

Colonel S. C. B. Robinson, principal medical officer of the Jubbulpore and Jhansi Brigades, has been appointed Principal Medical Officer of the First (Peshawar) Division. Colonel R. Porter, principal medical officer of the Western Command, has been appointed Principal Medical Officer of Malta, in succession to Colonel W. G. Macpherson, C.M.G. Lieutenant-Colonel W. G. Birrell, late senior medical officer at Mauritius, has been posted to the Eastern Command and appointed (temporarily) in charge of the Royal Herbert Hospital at Woolwich. Lieutenant-Colonel S. C. Philson has been appointed to command the station hospital at Bareilly. Lieutenant-Colonel C. T. Blackwell, from Woolwich, has embarked for a tour of service in India. Lieutenant-Colonel G. D. Hunter, D.S.O., commanding the Royal Army Medical Corps Depôt and School of Instruction at Aldershot, has been selected for the increased rate of pay under Article 317 of the Royal Warrant. Major G. B. Stanistreet has been transferred from the Southern Command for duty in the London District. Major J. B. Anderson, from the London District, has been posted to the Southern Command and appointed Embarkation Medical Officer at Southampton. Major J. V. Forrest has arrived home on leave from Egypt. Major C. K. Morgan has been transferred from Dundalk to Aldershot and appointed Instructor at the Royal Army Medical Corps Depôt and School of Instruction in succession to Major C. C. Fleming, D.S.O., whose tenure of appointment has expired. Major W. Hallaran, from the London District, has embarked for a tour of service in India. Major L. Addams-Williams has taken up duty at Tidworth Park. Major F. S. Penny, from Chatham, has been posted to Hong-Kong. Major G. B. Carter has been transferred from Dublin to Kildare. Captain

P. A. Lloyd-Jones has arrived home for duty from Malta. Captain H. E. Gotelee has been transferred to the home establishment from Ceylon. Captain G. A. D. Harvey, from Egypt, has been posted to the Eastern Command. Captain A. O. B. Wroughton, from Dover, has taken up duty at Canterbury. Captain L. F. F. Winslow has been transferred from Lichfield to Bradford. Captain W. MacD. MacDowall has joined at Devonport from duty at Willsworthy camp. Captain R. M. Ranking has taken up his appointment as Specialist in Advanced Operative Surgery to the Cork District. An exchange on the roster for service abroad has been approved by the War Office between Captain D. Ahern and Captain J. H. Gurley. Captain B. A. Craig has arrived home on leave from Hong-Kong. The following officers, on conclusion of their course of instruction for promotion at the Royal Army Medical College, have been posted as follows: Captain R. Storrs to Portsmouth; Captain F. A. H. Clarke and Captain R. Rutherford to Edinburgh; Captain G. A. K. H. Reed and Captain P. G. Easton to Aldershot; Captain H. V. Bagshawe to Leicester; Captain F. W. W. Dawson to Belfast; Captain J. E H. Gatt to Cosham; and Captain G. F. Rugg and Captain C. Ryley to Chatham. Captain W. D. C. Kelly has been appointed Specialist in Advanced Operative Surgery to the Dublin District in succession to Captain J. W. West, who has embarked for a tour of foreign service in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel J. W. Rodgers has been appointed to officiate as Principal Medical Officer of the Sirhind and Jullundur Brigades during the absence on eight months' combined leave of Colonel A. M. Crofts, C.I.E. Lieutenant-Colonel L. F. Childe, Bombay, has received an extension of his leave home from India. Major F. N. Windsor, chemical examiner to the Burmese Government at Rangoon, has been appointed to officiate as Chemical Examiner at Calcutta during the absence of Major J. A. Black. Major J. N. Macleod, on return from leave, has been appointed Civil Surgeon at Quetta under the Foreign Department in succession to Major F. A. Smith, proceeding home on leave. Major T. W. Irvine, on return from leave, has been appointed Civil Surgeon at Peshawar, vice Captain N. M. Wilson. Major V. B. Bennett, Madras, has received an extension of his leave. The services of Captain W. J. Collinson have been replaced by the Home Department at the disposal of the Commander-in-Chief. Captain A. W. C. Young has been reverted to military duty. Captain G. W. Maconachie has arrived home on leave. Captain E. J. C. McDonald, on return from privilege leave, has been posted as District Plague Medical Officer at Sialkot. The services of Captain A. S. H. Peebles, Officiating Superintendent of the Punjab Lunatic Asylum at Lahore, have been replaced at the disposal of the Government of India on relief by Major G. F. W. Ewens. Captain J. H. Murray and Captain W. M. Houston have arrived home on leave from the Bombay Presidency. Captain T. G. F. Paterson has been appointed to the medical charge of the 32nd Sikhs and 28th Punjabis. Captain G. G. Jolly has been granted eight months' combined and study leave home from India. Captain W. J. Powell has been appointed to officiate as Superintendent of the Central Jail at Jubbulpore, Central Provinces. Captain W. Tarr has been reverted to civil duty, and appointed to charge of the Nimar District Jail during the absence on special duty of Major W. H. Kenrick. Captain G. McG. Millar has been granted six months' leave on medical certificate. Captain W. F. Finlayson has taken over the duties of Superintendent of the Multan Central Jail. Captain A. D. Stewart has been appointed to the substantive Medical Charge of the Second Battalion of the 10th Gurkha Rifles. Lieutenant D. H. Rai has been appointed to officiate as Civil Surgeon of Jacobabad. Lieutenant S. C. Chuckerbutty has been appointed to the Plague Department in Burma.

TERRITORIAL FORCE.

Royal Army Medical Corps.

North Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant William M. Hewetson is seconded under the conditions of paragraph 114 of the Territorial Force Regulations (dated Sept. 25th, 1910).

3rd Highland Field Ambulance, Royal Army Medical Corps: William Latto Robertson to be Lieutenant (dated Oct. 19th, 1910).

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Edwin Augustus Houchin to be Lieutenant (to be supernumerary) (dated Oct. 12th, 1910).

Attached to Units other than Medical Units.—Lieutenant-William Duncan to be Captain (dated Sept. 26th, 1910). Lieutenant William M. Fergusson to be Captain (dated Oct. 15th, 1910).

For attachment to Units other than Medical Units.—Major Thomas Holt from the 2nd East Lancashire Field Ambulance, Royal Army Medical Corps, to be Major (dated Nov. 19th, 1910). Allan Freer Rutherford (late Captain, 4th Battalion, The King's Own (Royal Lancaster Regiment)), to be Captain (dated Nov. 12th, 1910).

DEATHS IN THE SERVICES.

Surgeon-Major-General James Sinclair, K.H.P., A.M.S. (retired), at Belfast, on Nov. 21st. He entered the army as assistant-surgeon in 1853, became surgeon in 1862, surgeon-major in 1868, deputy-surgeon-general in 1876, and surgeon-major-general in 1882, and retired ten years later. He served in the Abyssinian campaign of 1867–68 as surgeon of the 33rd Regiment, and was present at the storming and capture of Magdala. He acted as principal medical officer of a division of British troops in Abyssinia in the early part of 1868 (mentioned in despatches and promoted surgeon-major "for valuable services rendered during the campaign" (medal)). He also served in the Boer war of 1881.

Brigade-Surgeon-Lieutenant-Colonel John Ross Murray, A.M.S. (retired), on Nov. 17th. He entered the service in 1861 as assistant-surgeon, became surgeon in 1873, and reached the rank of brigade-surgeon-lieutenant-colonel in 1889. He retired three years later. He served in the New Zealand war of 1861, including the actions of Pataelakaurie, Mahoeten, and Matarikoriko (medal).

Staff-Surgeon James George Watt, R.N., who was drowned off Portland on Nov. 6th, was returning from leave during a strong south-westerly gale when the whaleboat which was conveying him to the gunboat *Gossamer* capsized. The body was washed ashore at Weymouth on Nov. 17th. Staff-Surgeon Watt entered the Royal Navy as surgeon in 1898 and was promoted staff-surgeon in 1906. He was attached to the *King Alfred*, the flagship of Rear-Admiral A. A. Galloway, commanding the Devonport Subdivision of the Home Fleet, but recently he had been temporarily transferred to the *Gossamer*.

SOLDIERS' TEETH.

The Army Council has issued a circular memorandum regarding the supply of artificial teeth to non-commissioned officers with long service. In future non-commissioned officers who have completed 21 years' service, and who are entitled to take their discharge after three months' notice, are *not* to be supplied with artificial teeth at the public expense. With regard to other cases, the general rule to be followed is that artificial teeth should *only* be supplied at the public expense when it is considered to be in the interests of the service to retain men whose service with the colours would otherwise be terminated on account of medical unfitness.

Correspondence.

"Audi alteram partem."

UNDERGRADUATES AND BEHAVIOUR.

To the Editor of THE LANCET.

SIR,—Your leading article this week on "Undergraduates and Behaviour" is certainly timely. The scenes now so prevalent at various university graduations are becoming little less than a scandal, and the good-humoured chaff and exuberance of the past on these occasions now gives way to boisterous hooliganism and indecent bad manners. The disturbances you report at Bristol, Edinburgh, and Cork are matched by the proceedings which took place at Glasgow this week, which were so gross as to be hardly credible.

In Liverpool the authorities manage these matters in an excellent way, and exert a happy control, with adequate liveliness and amusement to all concerned, while due dignity is preserved throughout the ceremony. It is high time that the Senates took adequate precautions to secure order, or agreed to prohibit the admission of the undergraduates to these functions. Something must be done, for these improprieties are becoming altogether too gross, and setting, as I believe, a very bad example to

the strata of society in these centres of learning who are as yet uninfluenced by what we ought to regard as the results of some degree of academic culture. It used to be thought that "manners made men." I much fear that discipline everywhere is sadly relaxed in these days, and the proofs of this are not far to seek.—I am, Sir, yours faithfully,

A MEMBER OF THE COURT OF THE UNIVERSITY OF LIVERPOOL.

London, Nov. 19th, 1910.

WHO IS HE?

To the Editor of THE LANCET.

SIR,—The Liverpool Medical Institution have in their possession a life-sized bust, a photograph of which is given below. The subject of the bust is unknown to them and they have been unable to identify it. It may be a replica of a marble bust in one of the Royal Colleges or hospitals. The

council of the institution will be very grateful to any of your readers who may be able to give them information towards establishing its identity.

I am, Sir, yours faithfully,

THOMAS BUSHBY.

Liverpool, Nov. 19th, 1910.

ERGOT AND THE PATELLAR REFLEX.

To the Editor of THE LANCET.

SIR,—Incidentally while seeing a patient a few weeks ago it occurred to me that the condition of the knee-jerk should be examined. The proceeding elicited the interest of an immediate relation who happened to be present and who asked if her knee-jerk also might be tested. Strange to say, it was in her case absolutely absent, though, as far as I knew, there had been no illness with nervous symptoms. But the history of the case brought to light the fact that this lady had been taking rather large doses of ergot for several years regularly for uterine fibromata and hæmorrhage.

I wondered if the ergot might have had any effect in this particular way and therefore wrote to Sir Lauder Brunton, who most kindly replied and referred me to Kobert's "Lehrbuch der Intoxikationen," Stuttgart, Encke, 1893, p. 440, where this passage occurs: "Die Symptome der Mutterkorntabes sind von denen der gewöhnlichen Tabes nicht wesentlich verschieden; der patellarreflex kann sehr zeitig verloren gehen." From this one concludes that ergot, when it causes nervous troubles, does sometimes bring about a series of symptoms closely resembling tabes dorsalis and that a very early sign of such a condition is the loss of the patellar reflex. Dr. J. Dixon Mann in his "Forensic Medicine and Toxicology," 1908, p. 668, states with regard to chronic ergot symptoms: "Psychical disorders, as hallucinations, delirium, mania, mental enfeebleness with stupor, and exceptionally, indications of tabes—lightning pains, girdle sensation, staggering gait, and unsteadiness in the erect posture with the eyes closed, have occurred. Tuczek found sclerosis of the posterior columns of the cord, implicating the root zones as in tabes." I presume that chronic troubles in connexion with ergot, whether they affect the nervous system or whether they be of a gangrenous nature, are primarily due to the blood-supply to the parts being cut down by resulting constriction of the blood-vessels.

I am, Sir, yours faithfully,

J. BIRT.

Belgrave-road, S.W., Nov. 15th, 1910.

INDEMNITY INSURANCE.

To the Editor of THE LANCET.

SIR,—The attention of the council of the Medical Defence Union has been called to the issue by the "Car and General Insurance Corporation, Limited," of a circular *re* benefits under an "Eclectic Policy," in which the name of the Medical Defence Union is used without our authority or consent and without any previous knowledge on our part that it was intended so to be used. I am directed to state for the benefit of members of the medical profession that the Medical Defence Union has no connexion in any way with the above company, and that it has not entered into any agreement with it whatever in respect of any such "indemnity policy," and that the only company authorised to use the name of the union in respect of any "indemnity policy" is the Yorkshire Insurance Company, Limited, Bank Buildings, Princes-street, E.C.

I am, Sir, yours faithfully,

A. G. BATEMAN,
General Secretary.

Nov. 18th, 1910.

To the Editor of THE LANCET.

SIR,—It has been brought to the notice of the council of the London and Counties Medical Protection Society, Limited, that indemnity insurance policies are being issued to members of the society (in respect of damages and costs of the other side in actions undertaken by this society) by the Car and General Insurance Corporation, Limited, and I am directed to inform members of the London and Counties Medical Protection Society that the Car and General Insurance Corporation has received no authority from this society, and that this society accepts no responsibility in the matter.

I am, Sir, yours faithfully,

HUGH WOODS.

31, Craven-street, Strand, London, W.C., Nov. 22nd, 1910.

CONTINUOUS PROCTOCLYSIS.

To the Editor of THE LANCET.

SIR,—Referring to a communication from Dr. H. W. P. Young concerning the use of the "Thermos" flask for continuous proctoclysis, I may mention that Messrs. de Luca and Co. (French Flint Glass Company), 6 and 7, Long-lane, E.C., manufacture for me an apparatus of a similar nature for use with a "Thermos" bottle. As this apparatus has kindly been shown in many hospitals in London by Dr. H. G. Mackenzie of Wimbledon, I have no doubt its merits and construtcion are fairly well known. Probably by ordering it through a wholesale chemist and sundryman any reader can obtain the apparatus in its perfect form as invented by me. In several medical papers last November notices of my having used the "Thermos" bottle were published, and the experimental part of the work, in order to bring this to perfection, has been carried on by me for over two years.

I am, Sir, yours faithfully,

LENNOX WAINWRIGHT.

Folkestone, Nov. 18th, 1910.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Medical Students' Hostel.

IT is proposed to establish a hostel for senior medical students in the immediate neighbourhood of the Manchester Royal Infirmary. "The object of the scheme is to enable students to gain experience in the management of accident and urgency cases, and in the observation of acute disease." This scheme, if carried out, as it will be, will give resident students opportunities that those living at a distance can never have. In Edinburgh, and in connexion with some of the London hospitals, such institutions have been successful and, it is said, self-supporting. The hostel will not interfere with the residential halls now existing, as it is only intended for medical students during the final period of their studentship. Such a hostel will, from its proximity to the hospital, provide opportunities for obtaining practical knowledge which will be available for students as they enter professional life, either as resident medical officers or assistants to private practitioners, or even if they venture forth at once into practice for themselves. It is proposed to start the hostel on a modest scale, providing for ten students at a weekly charge of 25*s.* each inclusive, and to give it a trial for three years. It will afford opportunities to students who cannot obtain resident appointments—for appointments are few and students are many—to get a much more practical knowledge of their work than if their hospital experience were limited, or nearly so, to the walk round the wards with the physician or surgeon in attendance. The scheme has the cordial support of numbers of influential people both in and out of the profession, and should be sure of success.

Typhoid Fever at Eccles.

A serious outbreak of enteric fever has occurred at Eccles, where up to last night over 90 cases had been reported. The parish church school has been closed for a fortnight, "there being 27 cases and over 100 contact exclusions." At the meeting of the education committee last night Dr. J. Orr remarked that the epidemic had assumed large proportions, but he was glad to say "the schools had been found not to be a source of infection, neither had anything been found wrong with the sanitary arrangements so far."

Surgical Aid Society.

The Manchester Surgical Aid Society held its annual meeting on Nov. 17th, the Lord Mayor (Mr. Charles Behrens) occupying the chair. Though very unobtrusive, the society does most valuable work among the poor, not only in relieving suffering but in helping discharged patients to help themselves. Last year 204 women, 138 men, and 99 children had been assisted in various ways. Appliances range from artificial limbs to belts, bandages, elastic stockings, surgical boots, leg irons, trusses, spinal supports, water-beds, and air-cushions. It may be mentioned that patients, with the help of friends, contributed £98 towards their cost. Still, as with so many charitable efforts, expenditure has exceeded income by nearly £35, though, notwithstanding the large amount of work done, the total expenditure was only £408. This society is indeed a necessary supplement and complement of hospital work, and Professor W. Thorburn was very emphatic as to the need there was for supplying surgical appliances to a great many poor patients, saying that surgery would be worse than useless if it had not the assistance of nurses and of the instrument maker. He thought that Manchester did fairly well by the hospitals and nurses, but that the citizens might do a little more for the society.

Anti-tuberculosis Fight.

It is encouraging to see that the struggle for the extermination of all the forms of tuberculosis is extending, and a step in advance was taken at Bolton on Saturday last. In connexion with the Bolton Guild of Help and the National Association for the Prevention of Consumption, a "tuberculosis exhibition" was opened by the Earl of Derby, in the Bolton Coöperative Hall. A special danger in manufacturing towns is that, working in the heated atmosphere of the mills, the operatives are hyper-sensitive to cold and chills, and so their rooms and cottages become stuffy and unhealthy from the closing, as far as possible, of every opening for ventilation. A similar state of things no doubt accounts to a large extent for the fact that Wales suffers, in proportion, more than any other part of the country from this disease. The air outside is fresh and pure, but inside the cottages it is too often fœtid and sickening.

Bolton Infirmary.

A King Edward memorial gift of £1000 has just been received by the treasurer of the Bolton Infirmary, being the fourth gift of a like amount, while several smaller sums have been sent.

Nov. 22nd.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol Health Committee.

Mr. Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., has been re-elected chairman of the health committee of the Bristol city council.

Bristol General Hospital.

The treasurer of the Bristol General Hospital has received £5000 from Mrs. W. Proctor Baker. This is the second moiety of the £10,000 promised to the institution by that lady in memory of her late husband, Mr. W. Proctor Baker, who was for many years president of the charity.

The late Dr. C. W. Belfield.

Dr. Charles Wooliscroft Belfield died recently at Bristol. The deceased was formerly a student at the Bristol Medical School, where he obtained the Sanders scholarship for surgery and medicine, and the Guthrie scholarship for medicine. He qualified M.R.C.S. in 1874, and in 1875 took the L.R.C.P. of Edinburgh. In 1884 he graduated M.D. of Vienna University. For many years Dr. Belfield had a large practice in Bristol, but a few years ago his health completely broke down, and he was forced to relinquish his practice. He was 58 years of age at the time of his death and unmarried. Dr. Belfield bequeathed £5000 to the funds of the Bristol General Hospital and £100 each to the Bristol Royal Infirmary and the Bristol Eye Hospital.

The Gloucestershire Memorial to the late King.

At a large and representative meeting, held at Gloucester on Nov. 12th, it was decided that as a memorial to the late King, a fund, to be called the "King Edward VII. Memorial Fund," should be raised in Gloucestershire, for the promotion of nursing in the cities, towns, and villages of that county.

The Cornish Memorial to the late King.

At a meeting held in Truro last week, under the presidency of the Earl of Mount Edgcumbe, it was decided to invite subscriptions for a "Cornwall King Edward VII. Memorial Fund." It is proposed to place a commemorative tablet in Truro Cathedral, and to invest the fund, applying the income thereof to any hospital, infirmary, sanatorium, or nursing association working in Cornwall as may be determined.

Gloucester Medical Charities.

The treasurers of the Gloucestershire Royal Infirmary and the Gloucester Children's Hospital have each received £5000 from the estate of the late Alderman George Peters, a former mayor of that city.

Nov. 22nd.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Death of Mr. George Arthur Brown, M.R.C.S., L.S.A.

THE sudden death of Mr. George Arthur Brown of Tredegar, while paying a professional visit to a patient on Nov. 17th, has caused profound sorrow, not only among the inhabitants of the immediate district in which he practised, but to the entire medical profession in Monmouthshire, for he was one of the oldest and best known practitioners in the county. He received his medical education at King's College, London, and after obtaining the diplomas of the Royal College of Surgeons and the Society of Apothecaries in 1865 was appointed house surgeon to the Sheffield General Infirmary, a post which he held for three years. He then came to Tredegar

as an assistant colliery surgeon, subsequently becoming chief surgeon, and retaining the position until the day of his death. He was certifying factory surgeon for the district, and district and workhouse medical officer of the Bedwellty union. As medical officer of health for the Tredegar urban district he was fearless in pointing out the sanitary needs of the district, and after agitating for many years for the establishment of a cottage hospital was finally successful in his endeavours, when in 1904 a well-equipped building with accommodation for 11 patients was opened by Lord Tredegar. He was on the commission of the peace for Monmouthshire and was at one time a member of the county council. He leaves a widow, one daughter, and two sons. One of his sons was associated with him in practice.

British Medical Temperance Association.

An address was given to the members of the Cardiff branch of the British Medical Temperance Association on Nov. 18th by Professor G. Sims Woodhead, who dealt with the relation of medical men to the alcohol question. He expressed the definite opinion that alcohol played an important part in determining disease, causing accidents and generally in regulating the number of patients who found their way to a hospital. He was convinced that alcohol was more prominently concerned than any other factor in degenerating diseases. While it attacked every tissue of the body, it attacked those of the highest development much more rapidly and with much more certainty than those of the lower. If alcohol could be replaced in medical practice by anything else he urged the necessity of refraining from using it, and if a medical man came to the conclusion that nothing else could be used it should be administered altogether as a drug and in definitely measured quantities.

Radnorshire Medical Officer of Health.

The Radnorshire county council has elected Dr. Laurence W. Pole county medical officer of health and school medical officer for the county. The combined salary of the two appointments is £300 per annum, with an allowance of £50 per annum for travelling expenses.

Gift of Sewage Works.

The entire cost of sewage works and a sewerage system for the colliery village of Seven Sisters in the Neath rural district has been defrayed by Mr. E. Evans Bevan, who is the owner of the collieries. The present population is about 2000, but the scheme provides for a considerable extension of the village.

Nov. 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow and West of Scotland Coöperation of Trained Nurses.

THE eighteenth annual report of this institution affords very interesting and instructive reading. The coöperation was the outcome of the rapidly increasing demands made by the public of the district for the services of fully trained nurses. At the same time the advantages for the nurses on the staff were to secure regular employment, adequate remuneration, and a central home. There are at present 195 nurses on the staff. The number of cases attended during last year was 2112, and the amount earned by the nurses was £12,580. Since the establishment in 1894 22,175 cases have been nursed and £132,455 have been earned. In the early years of the association 10 per cent. was contributed by the nurses to the association and this was afterwards reduced to 7½ per cent. Two years ago the scale of percentages was revised, and nurses now joining pay 10 per cent. for the first two years, and after the first two years 7½ per cent. Nurses who have been seven years in the coöperation pay 5 per cent. The association owns a house at Gourock, which is used as a residence for those nurses requiring a holiday. It was found that as the association became older the demands made by nurses for help during sickness steadily increased. A sick fund was formed and has now been put on a satisfactory basis. The capital account of this fund now stands at £3685. To this fund all nurses (with the exception of a few who are already members of the Royal National Fund) contribute £1 per annum. These contributions, along with the interest from investments and subscriptions from friends, have enabled the necessary payments to be made and a balance to be carried forward. Altogether the affairs of the association seem to be in a very flourishing condition, and it apparently fulfils in every way the purpose for which it was inaugurated.

Death of Dr. Thomas Lapraik.

In the person of Dr. Thomas Lapraik, who died last week, one of the oldest medical practitioners of Glasgow has passed away. A member of an old Glasgow family, he was born in 1835. He was educated at the Hutcheson School and Anderson's College, and finally graduated M.D. of Glasgow University in 1859. In 1873 he became a Fellow of the Faculty of Physicians and Surgeons of Glasgow, and for several years he was a member of its council. In addition to his large family practice Dr. Lapraik found time to devote himself to the advancement of medical education and to the welfare of several public institutions. For several years he was on the governing body of the Western Infirmary, Anderson's College Medical School, Lenzie Convalescent Home, and the Lock Hospital. He was also a manager of the Royal (Glasgow) Asylum at Gartnavel and of the Maternity Hospital, while for over 40 years he was physician to the Royal Glasgow Asylum for the Blind. Dr. Lapraik also served on the old city parochial board before its union in 1898 with the barony parochial board to form the Glasgow parish council. For some years he acted as convener of the medical committee, and during his period of office he secured many reforms in the arrangements for the nursing of patients in the hospital wards of the poorhouse. Outside of his medical work Dr. Lapraik was perhaps best known as chairman of the governors of the Glasgow Athenæum. The period of his chairmanship was perhaps the most critical in the history of the Athenæum, as it was during that time that the reconstruction scheme and the new constitution which placed the institution upon a permanent basis were carried through. On his retirement from the chairmanship his valuable services were recognised by the presentation of his portrait, a replica of which hangs in the reading-room of the institution. Dr. Lapraik is survived by his wife and a family of three sons and one daughter.

Reopening of Dundee Sanatorium.

Five young children from the Dundee Royal Infirmary were sent to the sanatorium at Auchterhouse last week. This fact was reported to the directors of the infirmary at their customary meeting, when it was also intimated that the 30 cots reserved for young children were now nearly all ready, and that a second contingent would likely be sent out soon.

Teachers' Protest against Medical Inspection.

At a meeting of the Deeside branch of the Educational Institute held at Banchory on Nov. 12th, the secretary read correspondence from the Garioch branch regarding medical inspection of school children. During the discussion which followed a good deal of feeling was shown regarding the amount of work demanded from Aberdeenshire teachers, all of which the medical inspector is doing in Kincardineshire. One Aberdeenshire teacher was reported to have flatly refused to perform the clerical work for which the medical officer was paid, with the result that the scholars had not been examined. It was resolved to have a representative meeting for all the branches in order to discuss the matter.

Medical Inspection of School Children in Caithness.

At a meeting held in Wick on Nov. 12th the secondary education committee of the county of Caithness again discussed the question of medical inspection of school children. Proposals for coöperation with Sutherlandshire had previously fallen through, and a scheme was put forward to appoint a medical inspector for Caithness alone at a salary of £300 per annum, the total cost for the first year to be £555. Mr. Robertson, chief inspector of schools, in pointing out that no provision was made in the scheme for coöperation with the county medical officer of health or for nurses, suggested that the scheme should be forwarded to the department for advice in certain local difficulties. This it was decided to do.

Death of Dr. Falconer Murison.

On Nov. 16th the funeral of Dr. John Falconer Murison took place at Cathcart. Dr. Murison graduated M.B., C.M., with first-class honours, at Aberdeen University

in 1875, taking his M.D. 20 years later. In his early professional career he was surgeon on board the Polar exploration vessel *Victory*. Dr. Murison then took up general practice at Walls, Shetland. Once he nearly lost his life through being attacked by enteric fever, a virulent epidemic of which he was fighting. His devotion won him the gratitude of a large number of the inhabitants of Shetland, among whom he was always welcomed on his visits to the island in later years.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Maintenance of Lunatics.

THE failure of the Treasury to pay the usual capitation grants for the maintenance of lunatics has naturally caused much anxiety throughout the country. As recorded in THE LANCET of Oct. 29th (p. 1313), an influential deputation, representing the various local authorities, waited on Mr. Birrell a few weeks ago to press the matter on the attention of the Government. In reply, the Chief Secretary asked for suggestions how to deal with the lunacy problem as a whole. At a conference in the Dublin city hall last week of representatives of the Irish county and borough councils, the Lord Mayor of Dublin presiding, certain resolutions were passed, and a deputation was appointed to convey to Mr. Birrell the views of the conference upon the questions dealt with. In the meantime, in the House of Commons Mr. Birrell, when questioned on the subject by Captain Craig, declared himself unable to make any promise of a minimum capitation grant, while Mr. Lloyd George informed Mr. Lonsdale that the question would be considered in connexion with the general problem of local and imperial taxation with which the Government was pledged to deal at the earliest opportunity.

Question of Suicidal Ward in Richmond Asylum.

A suicide having occurred some weeks ago in the Richmond Lunatic Asylum, the Inspectors of Lunatics made certain suggestions as to exercising greater care with regard to patients known to have suicidal tendencies. The most important of these suggestions was that a special "suicidal" ward should be established. In a special report to his committee of management, the resident medical superintendent of the asylum, Mr. J. O'C. Donelan, argued strongly against such a plan. He points out that the accumulation together of a number of acute melancholic patients would militate against their recovery. He also objects to giving written instructions on special points to attendants, as it tends to limit their attention to such points. Mr. Donelan in his management of the asylum follows the same principles as his predecessor and former chief, Dr. Conolly Norman.

Clinical Teaching in Dublin.

In the many discussions on medical education which have taken place in Dublin in the last few years there has been evident a certain discrepancy between the aims of the clinical teachers and those of the teachers of science. Some of the clinical teachers have been inclined to suspect a disposition on the part of their colleagues in the schools to trespass on the time set apart for hospital attendance. In Dublin clinical instruction begins each day at 9, and lasts till 11 or later. There has always, therefore, been an understanding that formal lectures in the schools should not begin earlier than noon. Breaches have been made in this understanding of late years, and in spite of assurances given by the school authorities to the hospitals two years ago, certain of the professors continue to lecture at hours which render regular hospital attendance impossible. The clinical authorities now threaten to invoke the assistance of the General Medical Council, but it is doubtful whether that body has power to interfere. The matter should be capable of ready settlement.

The Belfast Medical Students' Association.

At the inaugural meeting of the present session, held on Nov. 15th, the incoming President, Dr. W. W. D. Thomson, delivered an address on "The Country Doctor," and Professor J. A. Lindsay delivered an address on the Prospect before the Medical Student To-day, which has already been published in your columns.

Ulster Medical Society.

The annual dinner of the Ulster Medical Society took place in the Medical Institute, Belfast, on Nov. 18th. Dr. J. S. Morrow, the senior vice-president, in the absence through ill health of the president, occupied the chair. The chairman proposed "The King" and "The Lord Lieutenant and Prosperity to Ireland," to which the Lord Mayor of Belfast replied. Sir John Byers proposed "The Guests," to which His Honour the Recorder, Judge McIlroy, K.C., the Vice-Chancellor of the Queen's University of Belfast, and the President of the Ulster branch of the British Medical Association, Dr. W. Calwell, responded. Professor T. Sinclair gave the last toast—the health of the chairman, to which Dr. Morrow replied. Good musical selections were rendered during the evening.

Public Health in Belfast.

The Belfast corporation is promoting an omnibus Health Bill, and has given notice that in the ensuing session it will introduce the Bill. Among the clauses are a number of very important ones dealing with public health and sanitary provisions; some to obtain better control of women practising midwifery in the city of Belfast, others to confer further powers on the corporation with respect to meat inspection and for the better regulation of slaughter-houses, and for the seizure of tuberculous carcasses of meat.

Local Government Board Inspector.

Dr. Brian O'Brien has been appointed Local Government Board medical inspector in place of Dr. C. J. Clibborn, who shortly retires under the 65 years age limit. For Dr. O'Brien's posts in Belfast—divisional surgeonship of the constabulary, surgeonship to the Queen-street Children's Hospital, and medical attendant to Guinness's employees—there is a vigorous contest amongst the younger practitioners.

Surgeon-Major-General James Sinclair, M.D. Edin., Honorary Physician to H.M. the King.

On Monday, Nov. 21st, Surgeon-Major-General James Sinclair, M.D., a distinguished officer in the Army Medical Staff Corps, died at his residence, Cliftonville, Belfast, from bronchitis and heart failure at the advanced age of 79 years. Throughout his lengthened career in the army he was held in the highest esteem by all ranks, while in civilian life he was greatly liked for his social qualities. The funeral, with military honours, took place on Wednesday, Nov. 23rd.

Nov. 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Disorderly Behaviour of Medical Students.

DISTURBANCES similar to those of last year have occurred during the anatomical lectures of Professor Nicolas in the Paris Faculty of Medicine and have been carried so far that the professor was unable to make himself heard. An official notice has therefore been displayed on the walls of the buildings stating that the Dean of the Faculty of Medicine was making a final appeal to the students who have created disturbances in this lecture-room since the reopening of the classes, and that he was at the same time giving them a final warning. The dean assured the students that those of them who wished to work would be enabled to do so, that the authority of the professors would be fully maintained, and that he would take all the steps necessary for having offenders dealt with by the University Council. This notice had the effect of immediately putting an end to the disturbances, and M. Nicolas is now able to lecture without interruption.

The Dietetic and Physical Treatment of Epilepsy.

At a meeting of the Therapeutical Society held on Nov. 9th M. Deschamps described the dietetic and physical treatment of epilepsy. He said that since the time when auto-intoxication came to be regarded as a factor in the causation of epilepsy it had been recognised that bromides were not a panacea for the disease, that dietetic measures for the counteraction of auto-intoxication were valuable, and that an efficient action of the digestive organs was not less important. A further improvement was to supplement dietetic treatment by galvanisation and faradisation of the abdominal walls and to give baths of running water gradually cooled.

Action for Damages against a Medical Man.

Some months ago a married woman brought an action against Dr. Doyen, claiming 30,000 francs damages on account of an operation for spasmodic torticollis which he had performed on her gratuitously. The court having decided against her, she lodged an appeal, and when this was heard on Nov. 16th her counsel raised objections against the medical examination of the patient already made by three experts who had reported that she was recovéred. He asked that there should be a fresh examination by other experts, but the court refused this request, and upheld the decision arrived at in the previous trial.

The Depopulation of France.

At a meeting of the Société de l'Internat, held on Oct. 27th, M. Jayle, after describing the progressive diminution of the French population from the eighteenth century to the present day, said that the chief causes of it were the constant care bestowed on persons suffering from physical defects, together with systematic inattention to the interests of those who were healthy. Children of good constitution did not receive the same care and protection as sickly ones did, and the result was racial deterioration with a diminution in the number of children. Next in order of causation were certain social or industrial advantages which childless persons had over parents. Children were considered as a burden to be avoided; persons who had none were to this extent better able to engage in the struggle for existence, and obtained good situations more easily than heads of families did. A third cause of depopulation was the high mortality of the children of the poorer classes. M. Jayle considered that the best means of remedying these evils would be the imposition of a tax which he called the *impôt du sang transmis*. The effect of this would be that every man in fairly comfortable circumstances must, if he had not got three children, pay a yearly sum equivalent to the maintenance of one or more children in the class of society to which he belonged. A State institution for the assistance of families would have the duty of dealing with the funds raised in this way; the greater part of them would be distributed to poor families having three or more children, and the remainder would be applied for the benefit of various organisations for the protection of children. Another recommendation was that childless persons, who might on an average amount to one-fourth or one-fifth of the number of parents, should not be permitted to take more than one-fourth or one-fifth of the situations which were open to be filled.

The Rise of the Seine.

The river Seine has risen still further this week, but on Nov. 20th its level remained stationary or even fell a little. It was indeed high time, for notwithstanding all the measures of precaution that have been hastily taken, the flood water has done immense damage in the *banlieue*. Near the Austerlitz railway station the water has by degrees reached the line to Orleans. Thick walls which were built for the purpose are keeping back the rush of water, but there is more leakage than the pumps can remove. The water is steadily rising in the basement of the Palais de Justice, so that to get to the heating apparatus the attendants have to crawl along gangways almost touching the ceilings.

Nov. 21st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Paying Wards in Public Hospitals.

As already mentioned in these columns, a proposal was recently made in the town council to the effect that paying wards should be instituted in the municipal hospitals. The matter was then referred to a commission of the council, and according to the daily newspapers this commission has adopted the proposal and recommended that 7 marks 50 pfennigs (= 7*s*. 6*d*.) should be charged daily for each patient—1*s*. 6*d*. of this sum to be given to the physician or surgeon of the hospital in charge of the patient and the remainder being applied in repayment of the hospital expenditure on the case. For operations the surgeons should be entitled to charge a fee not exceeding 100 marks (£5). The medical officers of the municipal hospitals, on being heard before the commission, unanimously declined to accept this curious scheme, which they said would be prejudicial to the interests of the profession. It was probable that in the event of such wards being established in the municipal hospitals many patients of the middle, and even of the wealthy, classes would seek admission, knowing that they would be attended or even operated upon by leading physicians and surgeons of Berlin at ridiculously low fees, and in this way a good deal of practice among the middle classes would be withdrawn from the Berlin practitioners. It is not very likely that the proposals will be ultimately adopted by the municipal authorities.

Cases and Specimens shown before the Berlin Medical Society.

At a recent meeting of the Berlin Medical Society Professor Bockenheimer reported a case of extra-uterine pregnancy in which the patient complained of severe pains in the anus. On examination a small piece of a pointed bone was found penetrating the anterior wall of the lower part of the rectum, and a large cavity filled with bones was found in the pouch of Douglas. On a free incision being made, nearly the whole skeleton of a fœtus was then removed by the anal route. The patient made a good recovery. Professor Orth showed specimens of a case of extra-uterine pregnancy where an adhesion between the fœtal sac and the jejunum had formed; the legs of the fœtus had perforated the jejunum and the patient died from perforative peritonitis. Dr. Milchner showed a patient suffering from polycythæmia megalosplenica. He said that of 7000 patients examined in the out-patients' department of the Royal Medical Clinic three were cases of this disease. The patient shown at the meeting had a remarkable red colour of the face; it was not, however, for this that he sought advice but because he complained of dyspnœa and pains in the left hypochondriac region. Venesection proved useless, the numbers of erythrocytes increasing again after several hours; the application of X rays to the spleen was likewise unsuccessful, but under the use of a dietary containing as little ferruginous material as possible the quantity of iron in the urine, which had been eight times the normal amount, decreased and the patient's general state became better. The polycythæmia, however, remained the same as before.

Improvements in the Wassermann Reaction.

Speaking at a recent meeting of the Berlin Medical Society Dr. Saalfeld suggested that the requisites for the Wassermann reaction, which were of an inconstant composition, should be prepared in a central laboratory under State control. He alluded to the cases reported lately by Dr. Freudenberg in this society where the results of the reaction in tests made on the same patients and about the same time in different laboratories showed great discrepancies. He further reported that unqualified persons advertise in the daily newspapers that they were prepared to perform the reaction on application. He thought that these unfortunate occurrences would be avoided if the reagents used for the process were controlled by a competent authority on behalf of the State in the same way as the law directed with regard to antidiphtheria serum. In the discussion Professor von Wassermann said that there were some points of difference between the antidiphtheria serum and the extracts used for his reaction, because the former were of constant composition, whilst the latter were variable from one day to another. The extracts must therefore be examined every day. He had found a way of meeting the requirements of practitioners who were somewhat alarmed by the uncertain results obtained by incompetent examiners. He had made an arrangement with a chemical factory to prepare the extracts in question and to issue them to the medical profession. Examinations of these extracts will be made in his laboratory every day, and the factory will be informed as soon as a certain extract has proved inefficacious, so that the sale of it may be stopped. To prevent the reagents being spoiled by being kept too long after delivery only a very small quantity, sufficient for not more than five reactions, will be supplied to each purchaser. Several other members spoke against Dr. Saalfeld's motion, which was ultimately referred to a commission of the society for further inquiries.

Multiple Births in Germany.

According to the Statistical Year Book of the German Empire, quoted in the *Deutsche Medizinische Wochenschrift*,

26,314 cases of twin-birth were registered in Germany during the last year. In 8358 cases both children were boys, in 7843 cases they were girls, and in 9933 cases they were of different sex. Triplet-births happened in 261 cases, of which in 56 all the children were boys, and in 53 all were girls; in 72 cases there were 2 boys and 1 girl, and in 80 cases 1 boy and 2 girls. There were also registered 8 quadruplet-births.

Nov. 21st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Protection of Infant Life.

THE last census held in the year 1900 showed that the population of Hungary was slowly increasing, the annual increment tending to approach the analogous ratio observed among the Western nations. Further inquiries, however, disclosed the fact that the slow increase of the population was not due to a declining birth-rate but rather to the excessive mortality of infants and young children. This discovery resulted in a well-organised movement for the protection of infant life, which is at present being actively carried on all over the country. One part of the work of this organisation has been the establishment of institutions for the reception of children, and these have proved so successful that persons interested in the subject have undertaken long journeys for the purpose of seeing them. One of the most prominent leaders in the campaign against the excessive mortality among children is Dr. Menyhert Edelmann of Nagyvàrad, director of the local children's asylum. In a pamphlet recently published by him, entitled "The Campaign against the Great Mortality among Children," he writes that in 1907 the number of deaths in the country was 518,614. Out of this number, 231,498 were of children under 5 years of age, and 154,451 were of children under 1 year, which means that in Hungary practically every third person born dies within the first year of life. This rate has been maintained with little variation for several years past. Taking into consideration the absolute number of deceased infants, there is still less reason for satisfaction, because in 1907 more infants died than in any of the preceding eight years. The children's asylums (of which there are 19 in existence) have done good in various ways, but their effect has not yet made itself felt in a reduction of the death-rate. Dr. Edelmann maintains that the campaign against the mortality of infants will not be successful until the social and economical conditions of the people improve. As for the former, in Hungary there were 740,867 children born in 1907, and of these 72,628 (9·6 per cent.) were illegitimate. The number of stillborn children was 14,786. The deaths of 72,567 children were attributed to congenital weakness; of 7873 children to atrophy; and of 30,661 children to digestive disturbances. According to the Hungarian laws all children under 7 years of age must have medical attendance during an illness which proves fatal, but 50·7 per cent. of all the children who died were not seen by medical men, and there was medical evidence of the cause of death in only 56·6 per cent. of all the cases. The high proportion of illegitimate births was due to unfavourable social conditions rather than to wilful disregard of virtue. The great number of stillbirths points to the inadequacy of the attention given to women in childbirth. The leaders of the movement are unanimous in emphasising the great importance of breast-feeding in the reduction of infant mortality. They have stated that the mother's milk could not be wholly replaced even by a wet-nurse's milk, because there was a great biological difference between the two, and cows' milk was still less suitable. Mother's milk was the only food which changed in harmony with the gradual development of the infant and responded to the alterations going on in its digestive tract; mother's milk also conferred on an infant some degree of immunity against disease. There are therefore serious hygienic objections to the system by which mothers, who are capable of lactation, give out their children and seek positions as wet-nurses. On account of the ladies belonging to the upper classes being prejudiced against lactation wet-nurses are well paid in Hungary, their wages being from £2 4*s.* monthly with full board. In order to make mothers understand the iniquity of this system Dr. Edelmann organised a "School for Mothers" where popular lectures were delivered on pregnancy, childbirth, and lactation. The Minister of Internal Affairs has issued a popular pamphlet with the title "Good Advice for Women in the Expectant Stage and in Childbed, and for Mothers," and the distribution of this pamphlet has been entrusted to the parish priests and public notaries. In several large towns the so-called "free milk institutes" have been established, where milk is distributed to women of the poorer classes nursing their own infants. At the end of his pamphlet Dr. Edelmann makes several proposals which he recommends to the favourable consideration of the legislature. Some of these proposals are as follows: 1. A woman desirous of becoming a wet-nurse shall produce a certificate from a local magistrate stating that her last child is alive and is not older than 5 months. 2. The opening of agencies or registry offices for wet-nurses shall be licensed by the magistrates. 3. When a child under 7 years of age becomes ill medical advice must be obtained. Narcotics or similar drugs must not be given to children without the order of a medical man. 4. Women desirous of taking infants either for lactation or for attendance must notify their intention to a local magistrate. Without permission nobody may give out or take infants, not even a relative of the family. 5. No wet-nurse may take more than one infant at a time. 6. The artificial feeding of infants shall be strictly prohibited, with the exception that where the child suffers from an infectious disease the local magistrate may give permission for artificial feeding. 7. A nurse in whose care two infants or children of other mothers have died shall be removed from the list of recognised nurses. In the event of these proposals receiving legislative sanction the carrying of them into effect would devolve on the committee for the protection of infant life working as a section of the Ministry of Internal Affairs, with which is incorporated the Ministry of Public Hygiene.

Nov. 21st.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Illness of the ex-Sultan Abdul Hamid.

Abdul Hamid was always shrouded in mystery. During the long period of his reckless despotism nobody knew exactly how he was living or what he was doing in his sumptuous seclusion at Yildiz Kiosk, and the same uncertainty exists after his dethronement and exile. Where is Abdul Hamid at present? Many believe that he is no longer at Salonika, and that after the latest reactionary manifestations he was removed to Constantinople, and some think deported to Africa. Many, of course, ask, Is he living at all? This question is invariably answered by a certain sort of omniscient person with the statement that he has been poisoned long ago, that the authorities keep this fact secret in order not to excite unduly public opinion, and that recent news of his illness has been published by some of the Union and Progress party in order to prepare the Ottoman people to learn of their late ruler's final disappearance from the stage of the living. Quite a number, again, firmly believe that he has become insane. I have heard other omniscients describe him as hopelessly laid up with complete paralysis. Now, what is the real truth? Abdul Hamid is suffering from chronic prostatitis. He has never been completely cured from this disease. Four years ago, when Professor Bier of Berlin had been called to attend him, he refused to submit to the suggested treatment. The condition has since gone from bad to worse, and all medical men can imagine the train of sufferings which the deposed potentate is undergoing. Under the influence of this trying ailment his mental faculties have become disturbed. He does not want to see anybody, mistrusts his medical attendants, often gets into a state of uncontrollable rage, and is altogether an extremely trying patient as well as a sorely tried man. Such, I am informed on good authority, is the real state of the case.

The Epidemic of Cholera.

You will probably have published the admirably exhaustive statistics on the progress of cholera from the British Delegate on the Ottoman Board of Health.[1] The scourge is

[1] See THE LANCET, Nov. 19th, 1910, p. 1507.

unfortunately making increasing ravages, and especially so in the Ottoman army. It is asserted that the figures of deaths in the latter case, as officially reported by the authorities, are far below the actual numbers. It is believed that the epidemic originally showed itself among the soldiers who had been camping in very insanitary conditions on the hills of the left shore of the Upper Golden Horn. At present strict measures are being taken everywhere. It has been decided to assign another sum of a million piasters for purposes of combating the spread of the scourge. This decision has now been submitted to the sanction of the Sultan, who will, of course, not be slow in acceding to it. Conferences are being held in order to deliberate on the best means of stemming the progress of the epidemic. An extraordinary sanitary commission has been appointed in Scutari under the presidency of the governor of that district, Faik Bey. This commission is composed of six members, medical and lay, and it will visit in person the different quarters, and will give instruction to the public as to how to act in cases of cholera, indicating the necessary prophylactic measures after consultation with the municipal medical men. In Kadikeuy, not far from Scutari, all the residents and proprietors of houses, shops, baths, carriages, boats, &c., receive, after a visit from the sanitary authorities, a special card certifying that thorough disinfection has been carried out in the respective places. In the European districts of Pera, Galata, &c., the following measures have been taken. Every municipal circle has been divided into sections, each of which possesses a commission consisting of a member of the municipal council, a police agent, a gendarme, and a medical man, whose business it is to see that the streets, hotels, baths, and other public buildings are kept clean and properly disinfected. All negligence in hygienic matters and disregard of the municipal decisions and regulations will be punished. Every measure necessary to safeguard the population will be carried out at the expense of the municipalities. The Ministry of Public Instruction has sent a communication to the œcumenical patriarchate, asking him to comply with the decision of the superior sanitary council, and to make it compulsory that the drinking-water in all the Greek schools of the metropolis shall be boiled.

The Medical Faculty.

The students of the medical faculty are lodging various complaints against their professors, whose actions and decisions they consider to be arbitrary. The students are much dissatisfied with the new and strict examination rules, but it is impossible not to see that the professors have acted with the intention of improving the standard of medical education in Turkey. The medical students of the higher classes have submitted a protest to the Minister of Education, and it may be found that the changes in the curriculum have been made too suddenly.

Nov. 15th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The Fifth International Prison Congress.

THIS congress, recently held at Washington, proved a very important and successful meeting. There is much gratification over the endorsement by the congress of certain principles which occupy an important place here—viz., the indeterminate sentence on parole and the establishment of farm colonies for vagrants. On the whole, the reformatory aspect takes precedence in this country over the retributory and deterrent aspects of official punishment, and the sense of the congress seems to have favoured this attitude. It is to be remembered, however, that the homicide account of the country is disproportionately great; and if in that be included the vast number of deaths from industrial accidents of the distinctly avoidable class—for which someone should surely be, but rarely is, punished for criminal negligence—appallingly so.

Railroad Fatalities.

A most disquieting thing in this country is the terrible and increasing fatality roll of the railroads. According to the official report for the year ending June, 1910, there were 3804 people killed and 82,374 injured here during that period, an increase over last year, and this notwithstanding the number of precautions and safeguards the adoption of which in recent years it was hoped would reduce the annual record of such fatalities. Further, an unduly large proportion of these fatalities were of the avoidable kind; yet, although someone is thus clearly responsible, this responsibility seems not to have been adequately brought home to anyone in a single case. While tuberculosis, infectious diseases, diseases due to insanitary conditions all receive adequate and intelligent consideration and are vigorously combated in the United States, with a consequent lessening of the death-rate therefrom, the constant toll levied by industrial necessities seems to continue unchecked and even to increase.

Death of Dr. F. H. Wiggin.

Dr. Frederick Holme Wiggin, of New York, secretary of the Judicial Council of the American Medical Association, died at Atlantic City, N.J., on Oct. 28th. He was born at Kingston-on-Thames in 1853, but graduated in medicine in this country.

School Lectures on Tuberculosis.

It is announced that a course of lectures on tuberculosis will form part of the public school curriculum in New York city. Among the lecturers will be Dr. T. Darlington, Dr. H. Lorber, Dr. J. A. Miller, Dr. J. B. Huber, Dr. S. Adolphus Knopf, Dr. L. H. Klein, and Dr. J. Huddleston.

The Feeding of Public School Children in Chicago.

The School Management Committee of Chicago has attempted to grapple with the problem of the great number of underfed children of the poorest classes attending the public schools in that city. Lunch rooms are to be established in six of the largest public schools situated in districts densely inhabited by a foreign immigrant population. For 1 cent (½*d.*) as much soup and bread-and-butter as the children can eat will be given. An effort to make the scheme of educational value will be made by teaching the girls how to set and serve the food. The boys will be taught in the manual training department to make the "fireless cookers" in which the soup, made the preceding evening, is to be kept over night. As every hungry child will be fed, whether possessed of a cent or not, it will be interesting to note what proportion of cents to meals will be forthcoming.

Nov. 12th.

MEDICAL INSPECTION.—In regard to the scheme for the reorganisation of the school medical inspection staff agreed upon by the London County Council on Nov. 1st (see THE LANCET, Nov. 5th, p. 1364) the Education Committee has approved the appointment of Mr. J. A. H. Brincker, M.B. Cantab., D.P.H., and Miss Gowdey, M.B. Lond., two part-time officers, whose engagements have just come to an end, as full-time assistant medical officers (education) at commencing salaries of £500 a year. The first of a series of weekly returns as to the progress of medical inspection was submitted. It set forth: Number of school doctors engaged, 71; schools inspected, 73; children inspected, 5521; number found to require treatment (all ailments), 2369; number of those for whom treatment is available under the Council's scheme, 1558.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:*—Dr. J. H. Paterson, medical officer, Northern Nigeria, has retired on a pension, and Mr. W. S. Webb, medical officer, Gold Coast, has resigned his appointment, with a gratuity. Mr. D. Alexander, medical officer, Northern Nigeria, has been promoted junior sanitary officer, Sierra Leone; Mr. H. A. Foy, medical officer, Northern Nigeria, junior sanitary officer, Northern Nigeria; and Mr. J. B. H. Davson, formerly senior medical officer, Gold Coast, has been reappointed senior medical officer, Sierra Leone. The following gentlemen have been selected for appointment to the staff: Mr. P. C. Conran (Northern Nigeria), Mr. C. G. Grey (Southern Nigeria), Mr. J. P. B. Snell (Southern Nigeria).—*Other Colonies and Protectorates:*—Mr. C. K. Attlee has been appointed assistant to the colonial surgeon, St. Helena; Dr. A. K. Cosgrave has been appointed a house surgeon, Medical Department, Straits Settlements; Dr. F. W. Greaves has been appointed a supernumerary medical officer in Trinidad; Dr. H. M. C. Green has been appointed a medical officer in the Straits Settlements; and Dr. N. P. Jewell has been appointed an assistant medical officer in Seychelles.

Obituary.

JOSEPH FRANK PAYNE, M.D. OXON., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL; HARVEIAN LIBRARIAN OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

WE much regret to announce the death of Dr. Joseph Frank Payne, consulting physician to St. Thomas's Hospital, and one of the most learned members of our profession, which occurred at New Barnet, Hertfordshire, on Wednesday, Nov. 16th, in the seventieth year of his age.

Joseph Frank Payne was born at Camberwell on Jan. 10th, 1840, the son of Joseph Payne, the first professor of education at the College of Preceptors, whose learning and industry were well reflected in his son. Professor Payne, moreover, married a famous schoolmistress, so that on his mother's side also the subject of this memoir had an hereditary right to academic distinction. He was educated at home by his parents, and obtained a demyship at Magdalen College, Oxford, where he crowned a career of prize-winning with a first class in the Natural Science Tripos. Elected a Fellow of his college, he began his medical studies at St. George's Hospital, and graduated as M.B. Oxon. in 1867, while he won the Burdett-Coutts Scholarship in Geology and the Radcliffe Travelling Fellowship in Medicine. But he also graduated at the University of London as a Bachelor of Science in 1866, and took the Membership of the Royal College of Physicians of London in 1868. After attending clinics in Paris, Berlin, and Vienna with an industry that accounted for the wide range of his exact knowledge, he migrated from St. George's Hospital to St. Thomas's Hospital, where he was elected assistant physician in 1873, in which year he also became a Fellow of the Royal College of Physicians of London. In 1874 he was Goulstonian lecturer at the College, when he took as his subject the Origin and Relation of New Growths. Abstracts of these lectures will be found in THE LANCET and sufficiently show the range of his pathological learning at the time as well as his earnest spirit of research. The third of these lectures, which was devoted to answering the question whether cancer be a local or a constitutional disease, is a model of how to supply information without dogmatism. This was the beginning of a very close connexion with the College, where he was Lumleian lecturer in 1891, Harveian orator in 1896, and FitzPatrick lecturer in 1903 and 1904, while he was appointed Harveian librarian in 1899 in succession to Dr. William Munk. Of his FitzPatrick lectures we speak below—they more definitely than any of his work revealed him as archæologist and historian, but his Harveian oration showed the original bent of his great learning. He sketched on this occasion the course of mediæval medicine, and took occasion to do justice to Galen, whose errors have been much magnified, but whose methods of work Dr. Payne showed to be truly scientific.

In 1887 he became full physician to St. Thomas's Hospital, and in 1888 there came out the "Manual of General Pathology," the publication of which at once raised Dr. Payne to the front rank of medical men of letters. Until some 10 or 15 years before the publication of this book pathology was treated almost solely from an anatomical point of view even in the best of manuals, and one such work Payne had himself already edited. But the study of pathology had since that time received a grand impetus through the growth of the science of bacteriology, and in consequence Payne was able to include in his "Manual of Pathology" much description of vital processes where earlier authors had been perforce content with describing the products of disease. In particular in this manual was Payne able to handle the new subject of bacteriology with lucidity and exactitude, and the reception of his book was favourable immediately.

At St. Thomas's Hospital Payne made a favourable impression from the first. He at once identified himself closely with the interests of the place and became a son by adoption if not by birth. And yet in some ways he failed to reap the full advantage of his membership of the staff. He was elected at a more advanced age than is the rule, and promotion was unusually slow, so that he did not leave the out-patient room for the wards till within a few years of his compulsory retirement by lapse of time. Still, in the meanwhile he had made a name for himself not only in medicine but perhaps still more widely as one of the best known dermatologists in this country. "To the last," writes one of his colleagues, "it was over some rare skin disease that he would display his keenest interest." The same colleague adds: "As a teacher Payne was at his best with a small crowd rather than a large. For one thing, his voice was not strong enough to arrest the vagrant attention of the casual student, and for another he did not compel it by systematic resort to the Socratic method. But to those who cared to learn and whose interests were not limited to what might prove useful in the next examination he could be a most delightful teacher. As his Fitz Patrick lectures showed, there was hardly a bypath of medical lore that he could not illuminate, and perhaps the very variety of his knowledge made him less inclined to give systematic instruction." As an examiner, Payne was in much request, his great learning and natural kindness gave him the right blend of severity and tolerance, though his shyness sometimes infected the candidates. He was examiner in medicine at the Universities of Oxford, Cambridge, and London, and in 1899 became a Fellow of the University of London.

As historian and scholar Payne was not only a worthy representative of the University of Oxford, but a philosopher of whom medicine may well be proud. He possessed a sound knowledge of his profession in all its branches, being equally an authority upon general pathology, diseases of the skin and the infections, especially plague. In 1879 he went as a member of the British Commission for the Investigation of the Plague in Russia at Vetlanka, and his valuable observations of this epidemic were embodied in Vol. IV. of the Transactions of the Epidemiological Society of London (p. 362). Much of his experience was also contained in the careful and learned article on Plague which he contributed to Vol. I. of Allbutt's "System of Medicine." He embodied in a small book, entitled "Rare Diseases of the Skin," some valuable notes on interesting cases which had come before him in the course of his practice at the Blackfriars Hospital for Diseases of the Skin. He was at different times President of the Pathological Society of London, the Dermatological Society of Great Britain, and the Epidemiological Society, showing that in each of the branches of medicine where he especially worked his labours were appreciated by his colleagues.

But although the practical side of Payne's work in medicine was so valuable, he will be best remembered as a medical historian, a branch of literature for which both by training and temperament he was well fitted. The task of the medical historian is by no means easy. The ideal medical historian should be a good Greek, Latin, and Arabic scholar, as well as an expert in palæography, while in addition, if he deals with our own country, he should be able to read Anglo-Saxon, Welsh, and Erse. There is perhaps no one who can fulfil this ideal, and we do not mean to say that Payne did so. But he had a thorough knowledge of German and Latin and a working acquaintance with Greek; he had a passion for accuracy, a good memory, a scholarly mind, and a love for his subject which gave to his writings something of the innate beauty of the work of a mediæval craftsman whose handiwork and temperament are apparent in all his work. In 1901, when Mrs. Fitz Patrick expressed her wish to honour the memory of her husband by some foundation in the Royal College of Physicians of London, it was Dr. Norman Moore's advice which turned the gift in the direction of medical history, a subject in which he himself excels, and Payne was chosen by the College to be the first Fitz Patrick lecturer. He was already well known as a medical historian by the admirable article on the History of Medicine which he had contributed to the "Encyclopædia Britannica," by an edition of the De Temperamentis of Galen, and by his Harveian Oration.[1] Acquainted as he was with the brilliant and profound works on the history of medicine which foreign countries, notably Germany, France, and Italy, have produced, it was ever a matter for sorrow with him that his own country was so far behind others, not only in the bulk but in the value of its contributions to the history of medicine. Therefore no one welcomed the foundation of the Fitz Patrick Lectures more warmly than he did, for he saw in them, to use his own words, "the first attempt to have the history of medicine taught or expounded in this country." His introductory remarks to his first course of lectures may well be

[1] THE LANCET, Oct. 24th, 1896, p. 1134.

reproduced here, for they are characteristic of the spirit and power in which he undertook his task. After an enumeration of various "collections for the history of medical institutions," he continued: "But though these valuable materials for history have been collected, the amount is not very great, and the work of collating them has not been attempted. England is conspicuous among European countries for the zeal with which her political, social, and literary history has been investigated, and especially for the unrivalled series of records and memorials which have been collected for the purpose of such investigations. But the history of science generally, and especially of medicine and surgery, has been deplorably neglected. We have done little for medical history in general; but relatively almost less for our own medical history. The history of medicine in Britain, it is not too much to say, remains to be written. If in the standard medical histories we may sometimes think that British medicine is inadequately represented, this is not the fault of the historians. It is our fault for not having supplied them with adequate materials. ..... If we were to attempt, however inadequately, to lay something like the first stone of the history of English medicine: to make a rough beginning which, it is to be hoped, may be revised and corrected, as well as continued by other and better equipped investigators, this attempt, though humble, might not be without fruit." Such were the modest words with which Payne prefaced his admirable lectures on English Medicine in the Anglo-Saxon Times, delivered in 1903. These were followed in the second course delivered in 1904 by two lectures dealing with thirteenth century Anglo-Norman medicine, as exemplified by the work of Gilbertus Anglicus and Ricardus Anglicus. This course of lectures, much enlarged and expanded, is about to be published in book form, and on them Payne was working to within a few weeks of his death, and we earnestly hope that before long they may appear.

We have received eloquent testimony from Dr. Payne's colleagues at St. Thomas's Hospital as to their appreciation of his merits. "The better one knew him," writes one, "the deeper grew one's respect both for the man and for his really astonishing attainments. Of late years, partly through failing health and partly from his change of residence, his old colleagues have seen less and less of him; but on the occasions when he did again appear at the hospital his welcome was as warm as of old, and time has done nothing to dim his memory. One might take for granted his medical and pathological distinctions, even his classical knowledge and his familiarity with medical history of the remotest times, but it was almost paralysing to find by an accidental remark that he was the author of the 'Encyclopædia Britannica' articles on furniture, and that he was a connoisseur in china." There were, as a matter of fact, a dozen branches of knowledge upon any of which Dr. Payne could claim to be an expert, and yet the simplicity of the man was such that all his erudition seemed a matter of course.

GEORGE CARRICK STEET, F.R.C.S. ENG., L.S.A. LOND.

THE death of Mr. G. C. Steet, whom in our issue of Sept. 17th last we described as the Father of the Royal College of Surgeons of England, has taken place at his residence at Hampstead, at the age of 92 years. A student of St. George's Hospital, he became a Member of the College in 1840, and took the Fellowship in 1849, being the senior Fellow at the time of his death. He was chief medical officer at the General Post Office for 20 years, and held the posts of consulting medical officer of the Spanish Consulate in London, surgeon to the Home for Penitent Females, to the Royal Maternity Charity, and to Queen Adelaide's Lying-in Hospital. He was the author of articles on the Preservation of Food, the Ancient Mexican Treatment of Parturient Women, and the Development and Growth of Boys.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Olivier, formerly physician to the hospitals of Lille. Dr. M. K. Kassabian, a Röentgen-ray specialist in Philadelphia, from cancer caused by the action of the rays. Dr. Schönbrod, of Potsdam, from typhus fever contracted during laboratory research. Dr. Ernst Below, of Hanover, a well-known writer on tropical hygiene and the therapeutics of light.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

TUESDAY, NOV. 22ND.

THE General Council of Medical Education and Registration opened its winter session to-day at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, K.C.B., the President, was in the chair.

New Member.

Sir Isambard Owen, M.D., D.C.L., M.A., F.R.C.P., who has been appointed the representative to the Council of the University of Bristol for a period of five years from July 8th, 1910, took his seat. He was introduced by Dr. NORMAN MOORE.

President's Address.

Sir DONALD MACALISTER then delivered his Presidential address. He said: The latest addition to the academic family in England, the University of Bristol, has followed the good example of certain of its elder sisters by choosing a member of our profession to be its Vice-Chancellor. It has given further evidence of its wisdom by sending him to take his place here as a member of the Council. In Sir Isambard Owen we welcome an experienced administrator who has already done much for professional education in Cambridge, London, Newcastle, and Wales. We may safely count on deriving great advantage from his coöperation with us in the educational tasks that lie before us. His Majesty the King has been graciously pleased to confer the honour of a peerage on our former colleague, the Right Honourable Sir Walter Foster, who from 1887 to 1897 was one of the three members returned by the direct election of the registered practitioners of England and Wales. Lord Ilkeston has assured me that he will continue to interest himself in all that concerns the welfare of our profession. His Majesty has also bestowed the distinction of knighthood on one of our oldest and most assiduous members, Sir David C. McVail. According to the date of his first appointment he is the senior of us all, for no one of those who sat with him in 1886 is now a member of the Council. In the name of his present colleagues I have conveyed to him an expression of their good wishes, and their congratulations on the honourable recognition accorded his long and strenuous service as Crown representative for Scotland. In my Presidential address last May I mentioned that we might except soon to receive a new member from the University of Wales. It now appears that the University, though empowered by Charter to confer medical degrees and diplomas, has not yet procured from Parliament the legislative sanction which is necessary before these degrees and diplomas can be included in the list of registrable qualifications. The like authority is also required before the University can appoint a member of this Council. In my capacity as your representative on the University Medical Board, I have suggested that steps should be taken to obtain the powers in question, by the promotion of a Bill drafted on the lines of the Acts already passed in relation to Sheffield and Bristol.

During the summer death has removed, with merciful suddenness, Dr. Lombe Atthill from the dwindling roll of ex-members of the Council. He had held office among us for 14 years, and after his retirement in 1903 he continued to make useful suggestions to our committees, especially with reference to the branch of practice in which he was so eminent a proficient. Only a few days ago it was announced that Dr. J. F. Payne had also passed away. For five years he worked with us as representative of the University of Oxford, and those who knew him best will most regret the loss of one who did so much to maintain the scholarly traditions of the profession of medicine.

The wish expressed by the Irish Branch Council that an effort should be made for the extension of the Midwives Act to Ireland was duly communicated by me to the Government. I have reason to believe that in the Bill now under the consideration of Parliament the Lord President of the Privy Council has approved the introduction of provisions which will at least have the effect of removing the disabilities of midwives trained in Ireland.

It has not been possible to obtain assurances that an amendment will be accepted, providing for the prohibition of the practice of midwifery by unqualified men.

I have also official authority to state that the Parliamentary paper, setting forth the results of the Local Government Board's inquiries concerning the prevalence and the effects on public health of unqualified medical practice, is ready for publication. It will probably be issued before the end of this week. Copies will be placed in the hands of members of the Council at the earliest possible date. It is desirable that the conditions disclosed by these inquiries should be subjected to the fullest public discussion, so that the Council at its next meeting may be in a position to consider judicially what steps should be taken for their amelioration. Some progress has also to be reported with regard to the question of restricting the administration of anæsthetics by unqualified persons. The draft of a memorandum and Bill, submitted for the consideration of the Lord President, has been transmitted by his lordship to the Council for its observations. The Executive Committee has referred the documents to the special committee appointed by the Council, with the request that they will report to you on the subject during the present session.

It will be remembered that in 1901, at the instance of the Privy Council, Part II. of the Medical Act, 1886, was applied to Italy, with the result that Italian qualifications became registrable in the Foreign List of the Medical Register. Under the then existing Italian law British practitioners were accorded the right of practising among foreign residents in that country, but not among Italians. The relations thereby established were thus not fully reciprocal, though they conferred privileges of practice which at the time were regarded as valuable and in the circumstances satisfactory. Since then I have more than once, as occasion offered, pointed out to the Italian authorities that the concessions made from the British side were more liberal than those granted by the Italian law; and that it was desirable in the interest of the movement for reciprocity that the concessions in question should be equalised. It is gratifying to learn, from a despatch of His Majesty's Ambassador in Rome, which has been laid before the Executive Committee, that the Italian legislature has now passed an Act, of which the effect is to concede unrestricted freedom of practice in Italy to medical men duly qualified by registration in this country. As matters stand, the concession applies only to British practitioners, inasmuch as Britain alone has granted reciprocity to Italy. The Council may well be satisfied with the results of the liberal international policy adopted nine years ago. His late Majesty King Edward was graciously pleased to grant to the Faculty of Physicians and Surgeons of Glasgow permission to prefix the term "Royal" to the name of the corporation. The proper steps having been taken to give effect to the Royal grant I was requested to ascertain from the Law Officers of the Crown whether the Registrars of the Council required any further authority for employing the Royal prefix in registering the names and qualifications of Fellows and Licentiates of the Faculty. A definite decision has now been given that no further authority is necessary, and the Registrar has informed the Branch Registrars accordingly. Any practitioner already registered in virtue of a qualification granted by the Faculty may, on application, have the description of his diploma altered, so as to correspond with the style by which this ancient corporation is in future to be officially designated. In view of my own association with Glasgow, I may be permitted to offer from the chair my congratulations to the Royal Faculty, and to its President, Dr. Knox, on the mark of Royal favour.

With the approval of the Lord President I accepted an invitation, transmitted by the Privy Council, to attend in October a meeting at Berlin of the International Committee for the promotion of post-graduate medical education. The committee has been formed at the instance of the German Government for the purpose of coördinating and extending the facilities for special or advanced study and research offered in various continental countries to qualified practitioners, native and foreign. The committee possesses an international bureau, from which information concerning post-graduate courses, admission to clinical hospitals and laboratories, and other similar particulars of interest to practitioners, may be obtained. The members of the committee are nominated by the several Government authorities, but no permanent members have yet been added to represent the British Government, though provision is made in the constitution for such an addition should this country decide to take part in the organisation. As the result of my visit I reported to the Privy Council that in the interest of British practitioners, and in particular of officers of the medical services who might desire to visit the continent for purposes of study, and also in the interest of British institutions to which foreign practitioners might resort with the like object, it seemed desirable that our Government should avail itself of the opportunity to secure British representation on the international committee. I now understand that the authorities concerned will be prepared to give favourable consideration to any invitation in this sense through the usual diplomatic channels.

An important memorial will be laid before you, which is signed by a large number of influential persons concerned with the advancement of tropical medicine and hygiene, and supported by a communication from the Colonial Office. The subject has assumed a high significance of late years, both at home and abroad, in relation to the protection of health and life in many parts of the Empire. Instruction in the several branches of the subject has been provided at various centres in this country, and examinations for certificates of proficiency have been instituted by some of the licensing bodies. Value is attached to these certificates by the authorities who make appointments in the Navy, Army, Indian, and Colonial medical services, but at present no official machinery exists for ascertaining that the standard of proficiency which the certificates represent is maintained at a satisfactory level, or for registering those that are found to be deserving of recognition. The position resembles that occupied by diplomas in sanitary science State medicine, and public health before the Medical Act, 1886, was passed. That Act gave power to the Council to determine what diplomas deserve the recognition of registration. In the exercise of that power the Council has laid down rules for courses of instruction and examination which have proved of great service in guiding the teaching and examining bodies, and in satisfying public authorities that their diplomas are acceptable as certificates of high proficiency in the theory and practice of civil hygiene. The prayer of the memorialists is that steps may be taken to bring about a like result with reference to tropical hygiene, and it is pointed out that a slight amendment of Section 21 of the Act would effect this purpose. I have ascertained from the Privy Council Office, of which Lord Crewe, now Secretary of State for India, was lately the head, that should the Council favour the suggestion, a proposal to make the desired amendment could be laid before Parliament at an early date.

At the suggestion of the Local Government Board, the Pharmacopœia Committee appointed its secretary, Dr. Tirard, to attend an International Conference, held in Paris during the summer. The members of the Conference included delegates from a large number of Governments, and its purpose was to arrive, if possible, at a common understanding regarding methods and standards on questions relating to the analysis of food and drugs. Dr. Tirard has presented a full report of the proceedings, which will be communicated to the Council by the Pharmacopœia Committee. The Education Committee has in hand a report on the teaching of the subjects of chemistry, physics, and biology at institutions other than medical schools, and the relation of such teaching to the medical curriculum. The question of taking further steps towards raising the standard of preliminary examinations in general education has also been occupying the attention of the committee. From a number of licensing bodies communications have been received bearing on the separation of the subjects of medicine, surgery, and midwifery in the Final Examination. When the Registrar has received all the replies to the circular issued in pursuance of the Council's resolution of May 28th, 1910, they will be remitted to the committee for report. The Executive Committee, as instructed, is making necessary arrangements for the inspection in 1911 of the Final Examinations for qualifications in Dental Surgery. The committee proposes to appoint an inspector for this purpose, and to direct that the inspection shall be conducted under the regulations set forth in

Standing Order XXIII., so far as these are applicable to the case.

On the motion of Dr. LITTLE, seconded by Dr. NORMAN MOORE, the President was thanked for his address.

The late King.

A letter was read from the Home Secretary acknowledging the address of condolence presented by the Council on the occasion of the death of King Edward VII.

Commissions in the Indian Medical Service.

A table was received showing the results of the competition held in July, 1910, for commissions in the Indian Medical Service, and a motion proposed by Sir DAVID C. MCVAIL was carried expressing the thanks of the Council "to the Under-Secretary of State for India for the return which he has again furnished to the Council, with the request that such returns may in the future continue to be furnished to the General Medical Council."

The Diploma in Public Health.

Dr. NORMAN WALKER moved :—

That it be remitted to the Public Health Committee to consider and report whether any, and if so what, changes are called for in the regulations for the Diploma in Public Health.

He said that he wished simply to draw attention to the fact that a good many years had elapsed since the existing regulations were drafted and that circumstances had considerably altered in the meantime. Appointments had been made in connexion with the inspection of school children and the like, and the matter of the regulations was quite one which ought to be remitted to the Public Health Committee to consider. The regulations which were admirable 15 or 16 years ago might require revision now. Some people were of opinion that the regulations which the Council had drafted might possibly be made a little more definite than they were.

Sir JOHN MOORE seconded.

The motion was agreed to.

Diplomas in Tropical Medicine.

The Executive Committee brought before the Council certain communications and a memorial in regard to the registration of diplomas in Tropical Medicine.

A letter, dated Oct. 28th, 1910, was received by the Registrar from an official of the Colonial Office in the following terms :—

I am directed by the Earl of Crewe to inform you that his lordship understands that a memorial has been recently presented to the General Council of Medical Education and Registration in the United Kingdom in favour of the recognition of the Diploma in Tropical Medicine as an additional registrable qualification.

Lord Crewe, in view of the great importance of this branch of medicine to His Majesty's possessions in the tropics, desires to associate himself with the representations of the memorialists, and to express the hope that their request may be complied with.

I am to enclose a copy of a resolution in favour of the recognition of the Diploma in Tropical Medicine as a registrable qualification, which was passed by the Committee of the Tropical Diseases Research Fund at their meeting of 27th of May last.

The following extract from the minutes of the meeting of the Tropical Diseases Research Fund held at the Colonial Office in May last was attached to the letter :—

Sir Charles Lucas raised the question of supporting the memorial which had been addressed to the General Medical Council for the recognition of a Diploma in Tropical Medicine as a qualification for registration as a medical practitioner.

It was agreed that the Advisory Committee should strongly approve the proposal of the recognition of the diploma, and that their approval should be communicated to the Medical Council by the Secretary of State for the Colonies.

The following is the memorial in question :—

THE HUMBLE MEMORIAL, ETC., OF THE UNDERSIGNED SHEWETH

1. That in the year 1897 the then Secretary of State for the Colonies, the Right Hon. Joseph Chamberlain, instituted an enquiry into the character and extent of the education in Tropical Medicine then obtained by Medical Officers destined for Colonial service. As a result of these enquiries he pointed out to the Universities and the other medical educational institutions in Great Britain and Ireland the necessity for greater attention being given to the subject and, moreover, himself took an active part in the foundation of special schools for the teaching and study of this branch of medicine. Moreover, several of the already existing schools of medicine instituted special courses of lectures or courses of laboratory teaching in Tropical Medicine, thereby recognising the necessity of supplementing their previous curricula in this respect.

2. That the wisdom of this movement has been proved (1) by the increasing support extended by the authorities of most of the tropical colonies to the special schools referred to ; (2) by the number of students attending these schools annually—since its opening in 1898, 1046 students have passed through the London School of Tropical Medicine, 317 through the Liverpool School of Tropical Medicine, and about 28 annually through the Edinburgh School ; (3) by the fact that these students belong not to the Colonial Medical Services only, but to the Naval and Military and Indian Medical Services, to Missionary Societies, and to Planting, Railway and Trading Corporations, whilst a considerable proportion are private medical practitioners ; (4) by the subsequent establishment of similar schools in France, Germany, and America ; (5) by the number and importance of the recent additions to our knowledge of Tropical Medicine—additions in not a few instances attributable either to the students of these schools or to the stimulus given by these schools to the study of this particular branch of medicine ; (6) by the new light these advances in Tropical Medicine have thrown on many points in general medicine ; (7) by the more general diffusion of a correct knowledge of the methods of diagnosis and treatment of Tropical Disease ; (8) by the improved health of natives and Europeans in Tropical Countries.

3. It appears, therefore, to your petitioners that the time has come when this teaching should be encouraged by official recognition, that it should be regulated, and that the proficiency of the student should be officially certified.

4. That it is essential for this purpose that the General Medica Council should be empowered to regulate the courses of study and examinations prescribed for certificates in Tropical Medicine and to register such certificates as it finds deserving of recognition as additional qualifications.

5. That although certain bodies hold special examinations in Tropical Medicine, in only one instance—that for the M.D. examination, Section 7 of the University of London, open only to graduates of that University—is the special diploma registrable. The Universities of Cambridge, Edinburgh, and Liverpool grant diplomas in Tropical Medicine, and the Royal College of Physicians and Surgeons of England endorse certificates of proficiency in Tropical Medicine in the instance of their own diplomates ; but none of these diplomas or certificates are registrable as a special qualification. Moreover, there is no uniformity either in the standard of the examinations or in the range of subjects included. Even in the examinations for the various Public Health diplomas many important subjects in public health as relating to the tropics are ignored, notably the agencies peculiar to the tropics which transmit and spread certain diseases, subjects which hardly admit of being efficiently added to the present curriculum of the general medical student.

6. That the great and growing importance of the subject, the large number of medical men practising in the tropics, the number of qualified practitioners taking out special courses in Tropical Medicine, the interest in the subject taken by the government authorities in the tropics, the absence of special recognition of Tropical Medicine in ordinary medical examinations, and the special training necessary for efficient practice, justify your petitioners in requesting that a Diploma in Tropical Medicine should be recognised as an additional registrable qualification in the same manner as are the various diplomas in Public Health and Sanitary Science.

7. Your petitioners are further of opinion that the recognition and regulation of the various examinations in Tropical Medicine are essential for the securing of uniformity in the scope of such examinations and for the maintenance of such a standard of proficiency as would ensure that a proper value be attached to the diploma.

The memorial was signed by 68 persons, every one of whom, as a man of affairs, as a teaching or educational authority, as a physician, or as an expert in epidemiology, has a right to express an opinion on the matter.

The PRESIDENT moved the adoption of the following recommendations in regard to the communications and memorial respecting the registration of Diplomas in Tropical Medicine :—

(1) That the Lord President be informed that the Council is prepared to undertake the duty, should Parliament think fit to amend the Medical Act in the sense proposed ; and (2) that in the meantime copies of the memorial be forwarded to the licensing bodies concerned for their information, with the request that any observations they may have to offer may be communicated to the Executive Committee before its meeting in February next.

He said that the memorial deserved careful consideration. If the suggestion made were carried out in the form suggested it would involve a new duty on the General Medical Council. The Executive Committee thought that if the duty were imposed by Parliament the Council ought to undertake it. It was quite possible that some of the licensing bodies might have useful observations to make. These observations could be transmitted to the Privy Council along with the answer of the General Medical Council.

Sir THOMAS FRASER seconded. This, he said, was a very important matter, which certainly required consideration.

The motion was agreed to.

The Students' Register.

Dr. ADYE-CURRAN drew attention to the unsuccessful application from the Apothecaries Hall, Dublin, to have its preliminary examination re-scheduled. From communications received from the Privy Council he held that the General Medical Council was not authorised to publish a Students' Register. He suggested that no further expenditure on the Students' Register should be incurred.

The PRESIDENT replied that the expenditure on the Students' Register was quite legal. The keeping of a Students' Register was not one of the things which the Privy Council could compel the General Medical Council to do, but the Council could keep it if it thought the Register necessary.

The subject then dropped.

Restoration of Names to the Register.

After the Council had deliberated in private, the PRESIDENT announced that the Registrar had been directed to restore to the Medical Register the names of William Shaw, Percival Humble Watson, and Christopher Richard Kempster, and to the Dentists Register the name of Arthur Ogeesby.

The Council adjourned.

WEDNESDAY, NOV. 23RD.

The Council again sat at its offices, 299, Oxford-street, W., Sir D. MACALISTER, the President, in the chair. The whole of the sitting was devoted to the hearing of penal charges.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in October the following candidates were successful:—

THIRD M.B., B.S. EXAMINATION.

Honours.—*William Allen Daley, B.Sc., University of Liverpool; *Cicely May Peake, London (Royal Free Hospital) School of Medicine for Women; †Bernard C. Maybury, St. Thomas's Hospital; and *†Clement Edward Shattock, University College Hospital (University medal).

* Distinguished in Medicine. † Distinguished in Surgery.

Pass.—Alister R. Speirs Alexander, University College Hospital; Edward William Archer, B.Sc., and Jackson Arthur Atkinson, St. Mary's Hospital; Kenneth John Aveling, London Hospital; William Arthur Berry, St. Mary's Hospital; Sydney Guy Billington, University of Birmingham; Frederick Leslie Brewer, University College Hospital; Arthur Burrows, London Hospital; Arthur Neville Cox, Guy's Hospital; Robert Lawson Crabb, University College Hospital; Frederick Adolph Dick and Geoffrey Dunderdale, Guy's Hospital; Gerard Ferdinand E. Dyke, University College Hospital; Basil Franklin Eminson, Charing Cross Hospital; Thomas Charles Cann Evans, St. Mary's Hospital; William Charles Fowler, University College Hospital; Thomas Woodcock George, London Hospital; Abdul Hamid Gool, Guy's Hospital; Arthur Augustus Russell Green, University of Birmingham; Hugh Arrowsmith Grierson, University of Liverpool; Henry Pollard Hacker, B.Sc., King's College Hospital; Joseph Stanley Hopwood, St. Thomas's Hospital; Arthur Rocyn Jones, University College Hospital; Walter Shirley Kidd and Alfred Everard Lees, Guy's Hospital; Blanche Pattie Lindup, London (Royal Free Hospital) School of Medicine for Women; Dermot Loughlin, London Hospital; Kenneth D. Marriner, St. Thomas's Hospital; Raymond Montgomery and Gerald Thomas Mullally, Guy's Hospital; Eustace M. Parsons-Smith, St. Thomas's Hospital; John Valentine Rees, Cardiff Medical School and London Hospital; Arnold Renshaw, Victoria University of Manchester; Harold Ferdinand Renton, Guy's Hospital; Douglas George Rice-Oxley, London Hospital; Arthur Leyland Robinson, University College Hospital; Henry Gordon Smith, St. Bartholomew's Hospital; Robert Stout, Guy's Hospital; Ludwig Seibert Benjamin Tasker, University College Hospital; Leonard Herbert Taylor, Charing Cross Hospital; Gottfried Oram Teichmann, Middlesex Hospital; Graham Yalden Thomson, Guy's Hospital; Arthur Bayford G. Underwood, University College Hospital; Antonio Daniel Vazquez, Guy's Hospital; Michel Demétre T. Vlasto, University College Hospital; Lilian Enid Watney, London (Royal Free Hospital) School of Medicine for Women; and Ernest White, St. Bartholomew's Hospital.

The following candidates have passed in one of the two groups of subjects:—

Group I.—Norman Booth, Victoria University of Manchester; Arnold Charles S. Courts, University College Hospital; Hazel Haward Cuthbert, London (Royal Free Hospital) School of Medicine for Women; Walter Egbert Fox and J. T. Montgomery McDougall, Guy's Hospital; Emily Clara Macirone, London (Royal Free Hospital) School of Medicine for Women; Richard Naunton O. Moynan, University College Hospital; Mabel Muncey, London (Royal Free Hospital) School of Medicine for Women; and Thomas Anger F. Tyrrell, St. Mary's Hospital.

Group II.—Thomas Beaton, Charing Cross Hospital; Claude Alexander Birts, University College Hospital; Alfred Ernest Dagnall Clark, St. Bartholomew's Hospital; Maneckjee M. Cowasjee and John Adamson Edmond, Guy's Hospital; Florence Mary Edmonds and Ethel Rosaline Griffiths, London (Royal Free Hospital) School of Medicine for Women; Ernest Charles Lindsay, John Borland McVail, and Roy Kyffin Mallam, London Hospital; Alfred Arthur Edmund Newth, Westminster Hospital; Edward Au-ten Penny, Guy's Hospital; Alfred Alexander Webster Petrie, University of Edinburgh; David Scurlock, St. Mary's Hospital; and James Cowan Woods, London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—DENTAL EXAMINATION.—The following candidates have passed the first part of the Dental examination:—

Group A.—F. Horsley, H. McCormick, J. F. Mulligan, R. L. O'Grady, and S. Weinstock.

Group B.—A. Cohen, A. W. Mooney, J. J. Murphy, and S. Robinson.

The following candidates have passed the final examination and have been admitted Licentiates in Dental Surgery:—

C. W. Anderson, D. J. Doolin, S. Miller, R. T. Mosbery, and L. J. Smyth.

Prince Alexander of Teck presided at the court of directors of the Royal Sea Bathing Hospital on Monday last, when the committee reported that the new ward and day rooms were completed, and that there were now a few vacancies for male patients, but there were 20 female applicants on the waiting list.

THE next holiday course of the Berlin Association of Dozenten will begin on March 2nd, 1911, and will finish on March 29th. Prospectuses may be obtained gratis on application to Herr Melzer, Ziegelstrasse, 10/11 (Langenbeck-Haus), Berlin, who will also supply any further information that may be required.

BATHS AT TORQUAY.—There has been a considerable amount of discussion at Torquay in reference to the need of medical baths for the town, and it has been proposed to establish medical baths at the bath saloons. At the last meeting of the Torquay town council it was decided to send a deputation to visit several towns provided with medical and swimming baths and to report upon them.

THE BRISTOL MEDICAL SCHOOL.—At the annual dinner of the Bristol Medical School, to be held at the Royal Hotel, College-green, on Nov. 29th, Sir Alfred Keogh, K.C.B., late Director-General Army Medical Staff, is to be the guest of the evening. Applications for tickets (price 5*s.*) should be made to the secretaries of the dinner committee at the Royal Infirmary, Bristol.

THE HEALTH OF THE NATION.—The Lord Mayor of London will open a Conference of Health-Promoting Institutions, to be held at the Guildhall on Dec. 8th and 9th, which is being organised by the National League for Physical Education and Improvement. The subjects to be discussed include Schools for Mothers, Infant Welfare Schemes Abroad, Day Nurseries, Children's Care Committees, Health Societies, and the Coördination of Health-Promoting Agencies. Tickets of admission may be obtained gratis on application to the secretary of the League, at 4, Tavistock-square, London, W.C.

DONATIONS AND BEQUESTS.—Among a large number of charitable bequests the late Miss Dinah M. Dawson has left the following sums to be paid annually to the institutions named: Royal Infirmary, Edinburgh, £400; Royal Edinburgh Hospital for Sick Children (remembering especially the out-patient department), £400; Royal Maternity and Simpson Memorial Hospital, Edinburgh, £300; Royal Association for Incurables, Edinburgh, £300; Falkirk Infirmary, £400; Queen Victoria Jubilee Institute for Nurses, Edinburgh, £200; Edinburgh Deaf and Dumb Benevolent Society, £100; Glasgow Deaf and Dumb Benevolent Society, £100; Royal Blind Asylum and School, Edinburgh, £100; Victoria Hospital for Consumption and Diseases of the Chest, Edinburgh, £200; Home for Cripple Children, Edinburgh, £25; Samaritan Hospital for Women, Glasgow, £50; Edinburgh Medical Missionary Society and Livingstone Memorial Medical Mission Training Institute, £300; Blind Asylum, Glasgow, £100; Glasgow Royal Infirmary, £200; and Sick Children's Hospital, Glasgow, £200. The will also makes provision for the establishment or maintenance of a hospital for women in Edinburgh.—Mr. W. Knowles, J.P., has given to the Bolton Infirmary a donation of £1000 in memory of his late wife.—The executors of the late Mr. George Peters have given £5000 to the Gloucester Royal Infirmary and £5000 to the Children's Hospital, Kingsholm.—Mr. Maurice Rüffer has subscribed £150 towards the £8500 appeal for the Queen's Hospital for Children, Hackney-road, and has promised a further sum of £500 when the amount required has been obtained.—By the will of the late Mr. F. H. Harrison, the Boston Hospital, Lincoln, will, on the death of the testator's wife, receive £1000, Dr. Barnardo's Home £500, the Lincoln County Hospital £250, the Church Missionary Society for Medical Missions £200, and the Lincoln General Dispensary £100.—Miss A. Burrell has given £7000 towards providing a new out-patient building in connexion with the Royal South Hants and Southampton Hospital.—Mr. Thomas Wilkinson has given £1000 towards the enlargement of the Bolton Infirmary.—An anonymous donor has promised £5000 to start a fund for providing a sanatorium in Staffordshire as a memorial to the late King Edward.

THE NORTH KENSINGTON DISPENSARY.—On Nov. 23rd a meeting was held at the town-hall, Kensington, for the purpose of appealing to the public on behalf of the North Kensington Dispensary. The Duke of Argyll presided, and was supported by Lord Alverstone (Lord Chief Justice of England), Lord Claud Hamilton, the Mayor of Kensington (the Hon. Mr. Justice Phillimore), the Right Hon. Sir Alfred C. Lyall, P.C., Mr. W. Whitaker Thompson (Chairman of the London County Council), Sir Francis Fleming, K.C.M.G., Sir Arthur Clay, the Vicar of Kensington (Rev. Prebendary Pennefather), Miss Lena Ashwell, and others. The Duke of Argyll, in opening the proceedings, referred to the great progress that had been made in combating tuberculosis. Sir Arthur Clay, chairman of the North Kensington Dispensary, said that the annual cost was about £500 or £600. At the commencement Mr. W. C. Alexander had given £1000, and the Dispensary was started in March of this year. Since that time 379 tuberculous patients had received treatment or advice. To put the institution upon a sound financial basis it was necessary to appeal for public support. Mr. Alfred Hillier, M.P., said that nothing would stand out in the history of this epoch more than the progress which science had made in dealing with disease, instancing the names of Pasteur, Lister, and Koch. In dealing with tuberculosis the first piece of machinery required was the dispensary, and he appealed most earnestly to those present to support such an institution in North Kensington. He quoted statistics showing that London was behind other parts of the country in this branch of the treatment of tuberculosis, and hoped that the result of the present meeting would go a long way to do away with that reproach. Dr. G. A. Sutherland, medical officer of the St. Marylebone Dispensary for the Prevention of Consumption, referred to the regrettable fact that the more actively the campaign against tuberculosis was prosecuted the more there seemed to arise a feeling in the minds of the public against the consumptive, but the educated consumptive was absolutely no danger to the country. He pointed out that there was no necessity to send many of the early cases to a sanatorium. These cases could be better dealt with at a dispensary. This had been recognised by Germany. On the motion of Lord Alverstone, seconded by Mr. Justice Phillimore, a resolution approving of the work of the North Kensington Dispensary for the Prevention of Consumption was unanimously agreed to. Miss Lena Ashwell made a special appeal on behalf of tuberculous children.

THE AFTER-CARE AND EMPLOYMENT OF CONSUMPTIVES.—Under the auspices of the Charity Organisation Society a conference on this subject was held recently at Denison House, Vauxhall Bridge-road. Colonel Montefiore presided. Dr. Jane Walker (Maltings Farm Sanatorium) opened the discussion with a paper in which she said that the best occupation for discharged consumptives to follow was the one they had been employed at previous to treatment, because the most money could be thus earned and anxiety, a powerful factor in the diseased, was minimised. In some way all sanatoriums should be linked up together, and no patient should be discharged without knowing that he or she had a society or a friend in the neighbourhood to which they were going. Mr. William J. Fanning (Kelling Sanatorium) quoted statistics showing that it made little difference whether the discharged patient went back to indoor or outdoor employment. Hard work was not detrimental to the discharged consumptive if he had been carefully prepared for it before he left the sanatorium. Dr. Esther Carling (Kingwood Sanatorium) advocated the issue of a journal somewhat on the lines of a church parish magazine, but circulating among the ex-patients of all the sanatoriums, by which they could be kept in touch with their place of treatment and by which communication might be established between all persons interested in the question of tuberculosis. Dr. H. W. McConnel (Kelling Sanatorium) said that the shorter the time occupied by a patient in a sanatorium the greater the need for after-care. Dr. M. S. Paterson (Frimley Sanatorium) advocated the patient going back to his original occupation. Experience showed that most of the patients did very well in indoor occupations. Dr. T. Glover Lyon thought that it was the duty of the State to make some provision for discharged consumptive patients. It was absolutely cruel, he said, that consumptive patients should be thrown out into the world without being properly looked after. Dr. R. Maguire referred to the difficulty of getting work for discharged patients, and said that the public had been scared too much. Consumptive patients with no active disease when they left the hospital were not capable of infecting others if proper precautions were taken. Dr. Glover Lyon said that it would be wrong to employ a patient who had passed through a consumptive hospital or sanatorium in the capacity, for instance, of a housemaid, and thus risk the spreading of infection in the household. Dr. Jane Walker, in her reply, said she would not like to say that the public had been over-educated with regard to consumption, but rather that they had been wrongly educated. She was inclined to agree with Dr. Maguire that a patient might go back to work if he had no active disease.

MIDDLESEX HOSPITAL.—Prince Alexander of Teck has started a Children's Collection Fund in connexion with "The Prince Francis of Teck Memorial Fund" on behalf of the Middlesex Hospital. Books of numbered coupons, each coupon being in itself a receipt for 1*s.*, are being issued from the Middlesex Hospital to children who, with the consent of their parents, will collect for the memorial. The students of the Middlesex Hospital Medical School have resolved to raise amongst themselves the sum of 1000 guineas for the endowment of a Prince Francis Memorial Bed.

DEATH OF MR. MITCHELL HENRY.—The death is announced of Mr. Mitchell Henry at the advanced age of 85. Mr. Mitchell Henry, at one time the wealthy owner of Stratheden House, London, and Kylemore Castle, Ireland, took the Membership of the Royal College of Surgeons of England in 1847, the Fellowship in 1854, and was for a short time surgeon to the Middlesex Hospital. He retired early and entered political life as a moderate Home Ruler.

A REPORT has been issued from the Privy Council as to the practice of medicine and surgery by unqualified persons in the United Kingdom. The report, which is largely made up of information derived from medical officers of health, is preliminary, it is hoped, to the appointment of a Royal Commission to deal with the subject.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Situation.

THE political crisis, which is culminating in a dissolution of Parliament and a General Election, involves the abandonment of all Bills except one or two which the Government deems it expedient to pass to preserve the continuity of finance and administration. When Parliament reassembled on Tuesday, Nov. 15th, it was expected that the session would terminate before the end of the week. However, the Government decided to postpone the appeal to the country for a week and in the meantime to press forward the Budget and the Expiring Laws Continuance Bill. The effect of this decision is that all other Bills, such as the Midwives Bill, will automatically be dropped. Whichever party is returned to power at the General Election, it seems inevitable that the early months of the new Parliament will be devoted to dealing with constitutional questions of an acutely controversial character. In such circumstances the prospect of the advancement of minor departmental measures designed to effect administrative reforms would not bright.

Unqualified Medical Practice.

The report on the effect on public health of unqualified medical and surgical practice has been prepared and presented to the House of Commons by the Local Government Board. It is being printed.

HOUSE OF LORDS.

TUESDAY, NOV. 22ND.

Plague Rats in East Anglia.

Lord LAMINGTON asked whether, for the more effective destruction of rats in the plague-infected districts of East Anglia, the Local Government Board, as the chief authority, would not itself take steps for their extermination or else induce the local authorities concerned to adopt concerted measures under expert scientific guidance. The noble lord said that he had some experience of destroying plague rats in Bombay, and he put his question because so far as he could judge from the newspaper reports there seemed to be some lack of coördination on the part of the various authorities in their efforts to get rid of the trouble. He admitted that since he put the question down the latest regulations of the Local Government Board had in some degree met his objections, but he still had considerable doubts as to the methods adopted. Perhaps the noble lord who represented the Local Government Board would state what were the methods adopted by the local authorities and the Local Government Board to coöperate one with another in order to get rid of the rats.

Lord ALLENDALE, who replied for the Local Government Board, said the noble lord had drawn attention to a matter which required serious consideration and had given rise to considerable anxiety. After his experience in India the noble lord had shown a justifiable anxiety as to the extermination of these pests. He need not go into the details of the procedure adopted by the Local Government Board. The noble lord's question rather suggested that the Local Government Board should become rat-catchers, or at all events that the Board should superintend the extermination of all rats. The Board was of opinion that the campaign against rats should be of a local character, but it was fully alive to its responsibility in the matter of public health and had not been slow to press on the local authorities concerned the necessity of adopting common measures. From the outset the Board had provided the local authorities with guidance and advice. The matter was first brought to the notice of the Local Government Board on Oct. 3rd, when four cases of suspected plague were reported. The medical inspector of the Board was instructed on the same day to visit the locality and procure specimens, and this was done. On Oct. 8th a dead rat was sent to the Board for examination and on Oct. 12th was pronounced to have had plague. The inspector proceeded to make a scientific local investigation as to the extent of the disease and to give advice to the sanitary inspectors of the districts concerned as to the action to be taken. The Board also issued an order imposing the duty on sanitary authorities and providing for the appointment of additional officers and the necessary expenditure of money. The Board had taken other steps also, and arrangements had been made for a special staff from the Lister Institute to go to Suffolk and make an examination of rats on a large scale at various points, more especially as to the kind of rats affected and their special flea parasites. Up to the previous day only six districts were known to have rat plague in East Suffolk, one in West Suffolk, and one in Essex. This sort of outbreak had always been watched by the sanitary authorities and there seemed no particular reason why this particular work should be undertaken by the State. He did not think the State was better equipped in the matter of machinery or of being able to make experiments than were the local authorities. At the same time any advice which the Board could give would be at the disposal of local authorities, and the Board of Agriculture had issued leaflets on the subject. The Local Government Board and the Board of Agriculture were in coöperation and in touch with local authorities, and were prepared to give such advice as might be necessary.

Lord LAMINGTON asked how the central authority could see that these regulations were thoroughly carried out.

Lord ALLENDALE replied that the Local Government Board had been in touch with every district in which there had been the slightest suspicion of diseased rats, and, in addition to these regulations, the Board was receiving reports from all those districts of any suspected outbreak. The Board could not do more than it was doing at present.

The subject then dropped.

HOUSE OF COMMONS.

FRIDAY, NOV. 18TH.

Lead Poisoning Amongst Swansea Spelltermen.

Mr. CHARLES DUNCAN asked the Secretary of State for the Home Department what were the weekly hours of labour worked by the spelltermen in the Swansea district; whether his attention had been called to the prevalence of lead poisoning amongst this particular class of workmen as disclosed by the number of compensation cases for lead poisoning; whether he was aware that these men worked seven days per week during the whole year; and whether the Home Office proposed to take any steps to secure a reasonable curtailment of the hours of such workmen with a view to avoiding the dangers of physical destruction of the men concerned.—Mr. CHURCHILL replied: It is reported to me by the factory inspector of the district that the hours of labour of spelltermen averaged from 56 to 60 hours weekly. The process on which they are engaged is one that requires to be carried on continuously throughout the week. The number of reported cases of lead poisoning in the manufacture of spelter in the Swansea district during the last ten years was 99, of which nine were fatal. The number so far during the present year has been 12, of which one was fatal. The question of the health of the workers in this industry and allied industries has been engaging the close attention of the Factory Department. A special report by one of the medical inspectors was recently presented to Parliament and draft regulations based on his recommendations are about to be issued to the trade. The medical inspector has recommended that young persons under 16 and women should not be employed, but he did not find it necessary to recommend a limitation of the hours of employment of adult men.

The Maintenance of the Lunatic Poor in Ireland.

Captain CRAIG asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the intention of the Government as to the amount of State aid to be granted to the relief of local charges for the maintenance of the lunatic poor in Ireland; whether he was aware that committees of management of asylums in Ireland, having regard to the increased responsibilities and liabilities cast on them by the operations of the Local Government (Ireland) Act, 1898, which they assumed to the fullest extent in dealing with the insane in workhouses, acted in the assurance of a minimum 4*s.* grant; and whether, in view of the urgency of the matter, he would arrange that in future a minimum capitation grant of 4*s.* should be assured to all asylums.—Mr. BIRRELL answered: I am not at present in a position to make a statement on the subject or to say whether it will be possible to provide for a minimum capitation grant in future. The Local Government (Ireland) Act, 1898, does not contemplate such a grant in all circumstances, and the committees of management were not therefore justified in making the assumption referred to in this question.

WEDNESDAY, NOV. 23RD.

Sleeping Sickness in Nyasaland.

Sir J. D. REES asked the Secretary of State for the Colonies whether he had received information to the effect that two cases of sleeping sickness had occurred in Nyasaland in an area in which Glossina palpalis was believed not to exist; and whether any inquiries had been made into the matter and steps been taken to prevent the spread of the disease.—Mr. HARCOURT replied: I regret to say that the honourable Member has understated the case. I have received information of nine cases of sleeping sickness in Nyasaland, and there seems to be strong evidence that Glossina palpalis does not exist in the area in which they occurred, although I should hesitate to commit myself to a definite statement on the subject until the area has been further searched for the fly in question. The Acting Governor has already taken steps for dealing with the situation, of which he recognises the gravity, although he does not consider that there is at present cause for undue alarm.

BOOKS, ETC., RECEIVED.

AMERICAN CLIMATOLOGICAL ASSOCIATION (Secretary: Dr. Guy Hinsdale, Hot Springs, Va., U.S.A.).
Transactions of the American Climatological Association. For the Year 1910. Vol. XXVI. Price not stated.

APPLETON, D., AND CO., New York and London.

Births, Marriages, and Deaths.

BIRTHS.

BECK.—On Nov. 17th, at Bromyard, the wife of Ashton Beck, M.B., of a daughter.

CONAN DOYLE.—On Nov. 19th, at Windlesham, Crowborough, the wife of Sir Arthur Conan Doyle, of a son.

DANIEL.—On Nov. 14th, 1910, at 1A, Upper Wimpole-street, W., the wife of Peter Daniel, F.R.C.S., of a son.

WAGSTAFF.—On Nov. 19th, at Abington-street, Northampton, the wife of Frank A. Wagstaff, M.R.C.S., L.R.C.P., of a daughter.

WORTON.—On Nov. 20th, at Great Castle-street, W., the wife of A. S. Worton, M.D., F.R.C.S., of a son.

MARRIAGES.

BENETT—FAULKNER.—On Nov. 15th, at Bombay, India, Captain Arthur Morris Benett, R.A.M.C., of Jubbulpore, India, to Maude Elizabeth Faulkner, second daughter of the late Dr. J. J. Faulkner and Mrs. Faulkner of Dallington, Northampton.

CARNARVON-BROWN—KNIGHT.—On Nov. 16th, at St. Mary's, Petworth, by the Rev. A. J. Rendle (cousin of the bridegroom) and the Rev. J. T. Penrose, Rector, and the Rev. E. Frost, Arthur Carnarvon-Brown, M.R.C.S., London, younger son of the late Charles Brown of Carnarvon, Bournemouth and Queensland, and Mrs. Charles Brown of Bournemouth, to Kathleen Sherwin, only child of A. A. Knight, Esq., of Petworth, Sussex.

GRIFFIN—LITTLEJOHN.—On Nov. 17th, at Highfield Church, Southampton, John Purser Griffin, M.R.C.S., L.R.C.P., of Baldock, Herts, to Effie, eldest daughter of Frank Littlejohn of Westwood-road, Southampton.

WOLFE—PEARCE.—On Nov. 17th, at St. Mary Magdalene, Taunton, James Francis Wolfe, M.B., to Fanny A. B. Pearce, daughter of the late W. B. Pearce, Fleet Paymaster, R.N.

DEATHS.

BOLTON.—On Nov. 4th, 1910, at Blackpool, Dr. Frank Robinson Bolton, formerly of Birmingham, sixth son of the late Edward Bolton Interred in the family vault, St. Paul's, Warrington.

BROWN.—On Nov. 17th, at Tredegar, very suddenly of heart failure, George Arthur Brown, J.P., M.R.C.S., L.S.A., aged 67 years.

GOSS.—On Nov. 20th, at The Circus, Bath, Tregenna Biddulph Goss, M.R.C.S. Eng., aged 73 years.

PAYNE.—On Nov. 16th, at Lyonsdown House, New Barnet, Joseph Frank Payne, M.D., Fellow and Emeritus Harveian Librarian of the Royal College of Physicians.

ROSS MURRAY.—On Nov. 17th, at the Avenue, Gipsy Hill, S.E., John Ross Murray, M.D. Edin., F.R.C.S. Edin., Brigade Surgeon Lieutenant-Colonel A.M.S. (retired).

STIELL.—On Nov. 15th, at East Dulwich-road, S.E., John Stiell, M.D.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MALAY STATES' MEDICAL REPORT.

THE Federated Malay States are situated on the Malay Peninsula, and are closely connected with the Straits Settlements; they consist of the States of Pêrak, Selángor, Negri Sembilan, and Pahang, which have by treaty (1895)) renewed their engagements with the British Government, and are administered under the advice of a British Resident-General (Sir William T. Taylor, K.C.M.G.), who controls the residents subject to the instructions of the High Commissioner, who is also Governor of the Straits Settlements (Sir John Anderson, G.C.M.G.). The first three States are on the west coast, and Pahang on the east. All are governed by their native rulers under the above-mentioned control. The Resident-General's annual report for the year 1909 has just been issued from the Colonial Office. From this it appears that the number of patients treated in the hospitals was 73,192, as against 84,105 in 1908. The death-rate in the hospitals works out at 9·88 per cent. The decrease was general throughout the Federation, and cannot be regarded otherwise than with considerable satisfaction. The number of out-patients treated was 150,086; 25,675 patients were treated in Perak by the travelling dispensaries, and the same means of bringing medical aid within the reach of the natives is being introduced into Pahang, where a travelling dispensary has been established on the Pahang river. There were no cases of cholera or plague, and only five of small-pox. There were 68 cases of typhoid, with fatal results in 9 cases. There were 5 cases of blackwater fever, 2 of a very severe type ending fatally. Malarial fever was responsible for 17,386 cases, a decrease of 1000 cases as compared with 1908; the number of deaths was 936, equal to 5·38 per cent., a very satisfactory decrease. Constant attention is given to the matter of draining all swamps and similar places which might provide breeding grounds for the mosquito which transmits the parasite. The investigations of Dr. H. Fraser and Dr. A. T. Stanton have enabled the Government to combat with some success the very prevalent disease of beri-beri. The admissions amounted to 5469, with a death-rate of 12·05 per cent., as compared with 9790 cases, and a percentage of 19·52, in 1908. In all Government institutions the use of white polished rice is being discontinued and cured or parboiled rice is being substituted with very satisfactory results. Cases of dysentery and diarrhœa were 7197, with 1760 deaths, as compared with 9873 cases and 3263 deaths in 1908. Pulmonary diseases accounted for 3866 cases, as against 4209 in 1908. There was an outbreak of measles at Benus, in Pahang. 148 persons were attacked, of whom 8, all children, died from broncho-pneumonia following the disease. 33,782 persons were vaccinated. It is hardly possible to obtain an accurate figure of the percentage of successful operations, as a very large number of subjects never present themselves for subsequent examination. A hospital for Malays has been opened at Kuala Kangsar, and, in spite of some diffidence at the beginning on the part of those for whose benefit it is intended, has proved a marked success. 295 patients were admitted, of whom 51 were females. The outdoor department treated 1444 persons, and the medical officer in charge paid 87 visits to H.H. the Sultan, the native chiefs, and their families.

In regard to the Institute of Medical Research, Dr. Fraser, the director, was in charge throughout the year. Dr. W. Fletcher, the pathologist, went on leave in May, and Dr. Stanton undertook his duties in addition to his own work of bacteriologist. Mr. Eton, the chemist, remained in his appointment during the year. The greater part of the year was occupied with further research into the etiology of beri-beri, and it is satisfactory to record that the work has met with a considerable degree of success. Experiments on the lower animals with different kinds of rice have been carried out and will be yet further extended. The prevention of ankylostomiasis has received considerable attention. Dr. Stanton conducted a careful inquiry into the subject and submitted a very valuable report to the Government. Consequent on this a circular was drawn up by the director, in conjunction with the Director of Public Works, with plans attached, dealing with the question of latrine accommodation and water-supply. This was issued to all estate managers, who were invited to coöperate with the Government in eradicating and preventing infection with this scourge. In connexion with this matter Dr. Stanton also made a number of blood examinations of estate labourers and it was new to find a large number of parasites in the blood of coolies otherwise apparently healthy. The director states that, while drainage in low lands is attended by a marked improvement in the health of coolies, the same measures on high land seem to be comparatively useless.

M.O.H.—If the cycle is kept wholly for professional purposes our correspondent can deduct the cost of upkeep and possibly get an allowance for depreciation. A moderate sum would also be allowed for professional journals and subscriptions to professional societies.

A POINT IN EPISTAXIS.

To the Editor of THE LANCET.

SIR,—Some time ago a patient called at my place with bleeding from his nose which had been going on for some hours. I found a considerable flow from one nostril, and after syringing the cavity with no effect I proceeded to plug the nares, but the gauze was quickly saturated and blood dropped freely. I was at my wits' end when, whilst replugging, I found to my disgust that the hæmorrhage was coming from some dilated vessels on the external surface of the alæ on one side. The minute opening I cauterised and trouble was over.

I am, Sir, yours faithfully,

Innisfail, Queensland, Oct. 7th, 1910. ED. P. L.

WANTED, SUGGESTIONS FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—I should be greatly obliged if any of your readers could suggest an effective treatment in an obstinate case of Raynaud's disease in a young lady. All the usual remedies seem to have been tried without any apparent improvement. I am, Sir, yours faithfully,

Nov. 22nd, 1910. MEDICUS.

PANTOPON.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 5th your Swiss correspondent refers to a paper on "Scopolamine-Omnopon (Pantopon) Narcosis" by Dr. Brüstlein. With reference to the concluding remarks of your article, we would point out that it has now been ascertained that the solutions keep perfectly if kept in sterile ampoules, and the necessity for preparing fresh solutions as indicated by your correspondent is thus obviated. Ampoules of omnopon and scopolamine can now be obtained in the various strengths suggested by Dr. Brüstlein.

Yours faithfully,

THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD.

Idol-lane, London, E.C.

WANTED, A SCHOOL FOR BOY WITH SMALL LEARNING POWERS.

To the Editor of THE LANCET.

SIR,—Can any of your readers suggest a school, in the north of England or the Midlands, suitable for a boy of 13 years who is extremely deficient in learning power? He is a sensitive, nervous little chap, and his parents would like a school where he would be "mothered" to some extent. The boy is too bright to go to a school for really defective children, for he is quite intelligent to talk to and quite clean and healthy in his habits. He has a fair memory for things that have happened, yet cannot remember the alphabet nor learn to read. The father is a small farmer who could pay up to about £40 a year for tuition and board during school terms.

I am, Sir, yours faithfully,

Nov. 16th, 1910. COUNTRY MEDICO.

ERRATA.—"Kuatsu" and the "Heart Reflex of Abrams" (THE LANCET, Nov. 19th, 1910, p. 1502). Instead of "from 1 to 2 centimetres" read "1·2 centimetres." Instead of "from 2 to 7 centimetres" read "2·7 centimetres."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Dec. 8th and 9th (London, Guildhall).—Conference of Health-promoting Institutions and Fifth Annual General Meeting of the National League for Physical Education and Improvement.
" 19th–22nd (Rome).—Twentieth Congress of Internal Medicine.

In 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
April 19th–22nd (Wiesbaden).—Twenty-first German Congress of Internal Medicine.
May–October Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Pa ace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October(?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September Brussels).—Exhibition of Fractures.
Sept. 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 24th–30th (Rome).—International Congress on Tuberculosis.
" 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.

October (Cologne).—International Congress of Criminal Anthropology.
(Date not fixed) (Genoa).—International Exhibition of Marine Hygiene.

In 1912:—
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.

In 1915:—
(London).—International Prison Congress.
(London),—Imperial Exhibition (?)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—E. B. Dowsett, W. W. James, J. Howard Mummery): at 8 P.M.

Papers:
Mr. Frederick Sleep: Successful Surgical and Prosthetic Treatment of Excessive Hypertrophy of the Alveolar Processes of the Jaws.

Casual Communication:
Mr. H. A. T. Fairbank: (1) Endothelioma of the Jaw in a Child; (2) Cyst of Jaw (? Dentigerous).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Jonathan Hutchinson, L. A. Dunn): at 5 P.M.

Adjourned Debate:
On the Treatment of Fractures in the Neighbourhood of Joints (Mr. Robert Jones's paper). Mr. H. J. Paterson, Mr. Douglas Drew, Mr. C. H. Fagge, Mr. J. Hutchinson, Mr. W. H. Clayton Greene, and others will take part.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—G. F. Blacker, J. H. Targett): at 8 P.M.

Specimens:
Mr. J. Barris: Intestinal Obstruction caused by a Fibromyoma Uteri.
Mr. Douglas Drew: (1) Sarcoma of the Uterus; (2) A Case of Hermaphroditism.

Short Communication:
Dr. Louise McIlroy: Case of Hæmatosalpinx with Torsion.

Papers:
Dr. Archibald Leitch: The Pathological Bases of Operations on the Uterus.
Mr. Charles P. Childe: Twenty-three Cases of Wertheim's Abdominal Panhysterectomy.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—L. Hemington Pegler, W. H. Kelson), at 11, Chandos-street, W.: at 5 P.M.

Cases and Specimens
Will be shown by Dr. Scanes Spicer, Mr. C. A. Parker, Dr. L. H. Pegler, Dr. W. H. Kelson, Dr. H. J. Davis, Dr. A. Bronner, Mr. G. French, Dr. E. A. Peters, and others.

SECTION OF ANÆSTHETICS (Hon. Secretaries—R. W. Collum, Mrs. Dickinson Berry): at 8.30 P.M.

Paper:
Dr. Edwin Ash: Hypnotism in Relation to Surgical Anæsthesia.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Dilatation of the Heart and Heart Strain (introduced by Dr. Goodhart). Sir Douglas Powell, Sir Lauder Brunton, Dr. S. West, Dr. W. Collier (Oxford), Dr. Davy (Exeter), and others have promised to take part in the discussion.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Dr. R. J. Collie, Mr. G. C. Gardiner, Mr. W. D. Knocker, Mr. A. S. Morley, Dr. F. J. Smith, and others: Notes on the Workmen's Compensation Act, 1906.

RONTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY.—8.15 P.M., Dr. D. Butcher: Osmotic Growths.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Dr. Barnes: Motion—That Qualified Surgeon Dentists be admitted to the Society.—Clinical Cases.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersith.

FRIDAY.—8.30 P.M., Mr. J. E. R. McDonagh: Practical Experience with Ehrlich's New Specific for Syphilis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. L. Bunch: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. H. Stowers: Drug Eruptions, their Nature and Varieties.

TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M., Lecture:—Dr. T. D. Lister: Hæmoptysis.

WEDNESDAY.—4 P.M, Mr. J. Berry: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. W. Price: The Early Diagnosis of Pulmonary Tuberculosis.

THURSDAY.—4 P.M., Mr. L. H. McGavin: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Galloway: On Arterio-sclerotic Degenerations of the Skin.

FRIDAY.—4 P.M., Mr. D. Mackenzie: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Dunn: Purulent Conjunctivitis in the Infant and Adult.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Medical Registrar: Gastric Ulcer.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Morton: X Ray Examination of the Urinary System.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. Lloyd: Anæsthetics.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Prof. Hewlett: Antitryptic Power of the Blood and its Variation in Disease.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Anæmia.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

MONDAY.—5.15 P.M., Demonstration:—Dr. J. H. Thursfield: Food and Food Diseases—Congenital Pyloric Stenosis. (Special Post-Graduate Course.)

WEDNESDAY.—5.15 P.M., Demonstration:—Dr. J. H. Thursfield: Food and Food Diseases—Tuberculosis in Infancy and its Causes. Treatment of Milk intended for Infant Feeding. (Special Post-Graduate Course).

THURSDAY.—4 P.M., Lecture:—Dr. Frew: Pathological Demonstration.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Perkins: Pneumothorax.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture —Dr. G. Stewart: Subacute Combined Degeneration of the Spinal Cord.

FRIDAY.—3.30 P.M., Clinical Lecture:—Sir Victor Horsley: Indications for Operative Treatment in Intracranial Disease.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Dr. D. Grant: Methods of Examination.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Paratuberculides (due to Tuberculous Toxins)—I., Macular, II., Papular; III., Pustular; IV., Pigmentary.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. C. H. Melland: Epilepsy. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (3rd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Purbis Oration

ON

THE TREATMENT AND PROGNOSIS OF EXOPHTHALMIC GOITRE.

Delivered before the West Kent Medico-Chirurgical Society on Dec. 2nd, 1910,

BY W. HALE WHITE, M.D. LOND.,
SENIOR PHYSICIAN TO GUY'S HOSPITAL.

GENTLEMEN,—When I look down the list of those who have in previous years delivered this oration I feel much flattered by being asked to give it, and can assure you I thank you heartily for having invited me. It is a particular gratification to me, for the first orator was my teacher and friend, that fine surgeon and excellent man Arthur Durham.

The subject I have chosen, with the consent of your secretary, is one about which the teaching as to treatment is very various; if a surgeon writes about exophthalmic goitre he usually conveys the impression that most of the patients ought to have a considerable part of their thyroid gland removed or rendered functionless; on the other hand, the physician most often advises that this should not be done. Further, many authors leave us much in the dark as to what becomes of the sufferers from exophthalmic goitre. Nor is this surprising, for it is usually a chronic disease, and those who have it often pass out of the notice of those who first observed them. It is often forgotten that before we can tell whether any particular treatment is good or bad we must know what would happen to the patients if no treatment were adopted. Something may be learned about this if we trace the after-history of hospital patients, because after they have left the hospital and gone to their own homes in most cases very little systematic treatment is possible.

PROGNOSIS.

My clinical assistant, Dr. Jan Mahomed, kindly wrote to all the hospital patients, 148 in number, who had been in Guy's Hospital during the years 1888–1907 (both inclusive) suffering from exophthalmic goitre and who had been discharged. Many had moved, many did not reply to the letters, but 54 could be traced. Now of these 54 there were 12 who did not improve at all during their stay in the hospital, and yet ultimately got quite well or nearly well. This cannot have been due to the shortness of their stay in the hospital, for the number of days which each respectively remained in the hospital were 49, 14, 11, 36, 14, 95, 46, 58, 55, 45, 170, and 9, which gives an average stay of 50 days. I will not weary you with reading the history of each of the 12 cases, but let me mention a few.

CASE 1.—A woman, aged 20; in the hospital 49 days; no better on discharge but gradually got better; has worked hard for last 18 years. After leaving the hospital she married and had three children and is now a widow. Is quite well and has had no special treatment.

CASE 2.—A woman, aged 20; a severe case; in the hospital 58 days; no improvement; heard of five years after and is very much better and in a situation as a lady's maid.

CASE 3.—A woman, aged 42; was in the hospital 55 days; average case; had had the symptoms three years. No better on discharge. Heard of four and a quarter years after when she was wonderfully better.

CASE 4.—A woman, aged 34; was in the hospital 170 days; average case; had had the disease one and a half years. No improvement in the hospital; was able to work four months after discharge; heard of four years later when she said she was quite well.

CASE 5.—A woman, aged 19; was in the hospital 36 days; had had the disease one and a quarter years; average case; only slight improvement on discharge eight and a half years ago. Is now quite well and has been in service five years without a single day's illness.

CASE 6.—A woman, aged 42; in the hospital 46 days; mild case; no improvement on discharge. Came up to show herself five and a quarter years after; much better; hardly any signs of the disease left.

I have thus given you brief details of six of the 12 cases, and in the other six the story is the same. They certainly seem to show that in some persons at least there is a natural tendency for exophthalmic goitre to get well. No doubt this operates more often than these figures show, for it must have helped some of those who improved while in the hospital. We also learn that some who are afflicted with this disease recover without treatment. We rarely see death due to exophthalmic goitre, and we do not often see elderly women with it. These two facts illustrate the natural tendency of the disease to get well.

But it might be the reason why we do not often see elderly people with it is that although the malady itself does not often kill, yet sufferers from it are bad lives, inasmuch as they die more readily than most people from other diseases. About 25 years ago I published a few cases that I had followed up for some years which appeared to show that this was so; now I have tried to come to a more certain conclusion by following up a much larger number of cases. I shall at present deal only with cases which have not been operated upon.

I have been able to trace with the help of Dr. Jan Mahomed 49 patients who have been in Guy's Hospital during the 20 years 1888–1907 (inclusive), and I myself, with the hearty coöperation of their medical attendants, have been able to trace 53 private patients first seen between the years 1894–1909. Among the 49 hospital patients 8, and among the private 7, are now dead. I submitted my figures to my friend Mr. H. C. Thiselton and he has given me an actuarial report.

First, concerning the hospital cases. A comparison of the actual deaths was made with the expected deaths according to the Healthy Females Experience of 20 British offices amongst assured lives. The comparison shows that the total number of deaths was 8, as against 5 according to the experience of 20 British offices.

Secondly, as regards the 53 private patients the comparison shows that the total number of deaths was 7, as against 3 according to the experience of 20 British offices.

Putting the two groups together we see that the total deaths were 15, but the expected deaths among the same number of women of the same ages and followed up for the same time was according to the Healthy Females Experience table 8.

These figures suggest that if it were possible to obtain a great many more cases we should be able to prove that the expected mortality of sufferers from exophthalmic goitre not operated on who have been in a hospital and have been discharged and of sufferers from it in private practice who sought a second opinion (for all the private patients were referred to me by their usual medical attendant) would be about twice as great as it should be. In other words, sufferers from exophthalmic goitre are to some extent bad lives, but when we say that the mortality among them is about twice that of healthy women of the same age we must remember that those who have exopthalmic goitre are usually of such an age that the number of expected deaths among the healthy of that age for the next few years of their life is not great, therefore the increased number of deaths among those who have exophthalmic goitre does not represent a serious mortality. Too precise conclusions must not, however, be drawn from these figures, for all the cases here considered were either ill enough to come into hospital or to seek a second opinion. If all cases, and therefore many mild cases, of exophthalmic goitre were considered, the difference between the expected deaths among healthy women and those with exophthalmic goitre would doubtless be smaller. On the other hand, the comparison just made neglects those who died in the hospital with exophthalmic goitre; the inclusion of them would accentuate the difference between the expected deaths among the healthy and those among sufferers from exophthalmic goitre; but if we included in our comparison all those who in 20 years died in the hospital with exophthalmic goitre we ought to include all those who had been in the hospital and could not be traced, and the inclusion of them would diminish the difference between the expected deaths among the healthy and those with exophthalmic goitre which had been increased by the inclusion of those who had died in the hospital. It seems, however, a fair conclusion that the expected deaths among sufferers from exophthalmic goitre is somewhat, but not very much, greater than among the healthy—in other words, they are rather bad lives.

This conclusion leads us to our next inquiry—namely, the cause of death among those who have this disease. Still excluding those who were operated on I have notes of 18 cases of patients who died in Guy's Hospital. Eleven of these had either vomiting or diarrhœa, or both, and in many these were either the cause of death or contributed to it. For example, there is the case of a woman, aged 31, with special symptoms of palpitation, vomiting, and diarrhœa. These persisted, and after death gastro-enteritis was found. The next patient on my list was in the hospital 60 days.

Vomiting and diarrhœa set in, progressed, and killed the patient. After death gastro-enteritis was found. Both these cases had a rare symptom—namely, jaundice. This was no doubt catarrhal and due to the gastro-enteritis. I need not weary you with details of the other 9 cases. I know the cause of death in 7 private cases and in only 1 was it owing to diarrhœa and vomiting. This difference is no doubt due chiefly to the fact that private patients are more likely than hospital patients to seek treatment for vomiting and diarrhœa early. Both these symptoms are by no means uncommon in exophthalmic goitre, and the cases here quoted point strongly to the fact that the patient should be put to bed and be suitably treated directly vomiting or diarrhœa show themselves.

Combining the deaths among hospital and private patients, 6 died delirious, 1 became comatose, 2 had melancholia, and 1 had mania. We are thus reminded of the association of an unstable nervous system and exophthalmic goitre. Three had endocarditis, 1 had pericarditis, 2 died from rheumatic fever, and 1 attributed the disease to it. These illustrate the association between acute rheumatism and exophthalmic goitre. Two died from diabetes. It is well known that glycosuria occurs in association with exophthalmic goitre and so two deaths from diabetes hardly surprise us, but sometimes, as the exophthalmic goitre gets better, the accompanying glycosuria passes away. Thus I know a woman who nearly 20 years ago had glycosuria and exophthalmic goitre. The glycosuria passed away as she slowly recovered from her exophthalmic goitre and she is now perfectly well and has been so for 15 years at least. A smaller percentage of private than of hospital patients die, but that is what might have been expected considering that rest is the most important part of the treatment.

AFTER HISTORIES.

Let us now consider what becomes of those patients who are not operated upon and who do not die. I have been able to find this out with regard to 40 of the patients who were in the hospital from 1888 to 1907 and with regard to 47 of the private patients seen between 1894 and 1909. I have grouped them into three groups: (*a*) Those who have done well; (*b*) those who are moderately well or simply describe themselves as better; and (*c*) those who are not well. The following table shows the result:—

	Done well.	Moderately well.	Not well.
40 hospital cases	26	12	2
47 private cases	35	9	3

This is a very satisfactory result, especially as the cases have been traced for so long a period since they were first seen. Out of 87 cases 61 have done well and only 5 have not done well. In order to prove to you that the cases which are said to have done well really are well I will give you a few examples. Taking first the hospital cases—No. 1: The patient has required no treatment since he left the hospital 21 years ago. No. 4: This was a bad case; in the hospital 20 years ago; since has worked hard for 18 years, has married, has had three children, and is now a widow. No. 6: In the hospital 20 years ago; since then has worked as a district nurse. Subsequently married and has four children. No. 9: In the hospital 16 years ago; feels quite well; has not had a doctor for 12 years. No. 15: Was in the hospital 11 years ago, had had the disease for ten years; after leaving the hospital, since when she had had no treatment, she has married and has six children. No. 18: In the hospital 8½ years ago; is now quite well and has been in service for five years without a single day's illness. No. 24: The patient is included in this group as she is able to go to work. No. 25: Is working as a cook. No. 29: This patient does not know there is anything the matter. No. 32: Patient is now quite well and has been so since her discharge. No. 34: The patient is "wonderfully better." No. 35: The patient is perfectly well. No. 37: Patient has had no return of her old complaint and is married. No. 40: Was in the hospital 8¼ years ago; has been well ever since she left the hospital; went into service for four years, then married, has four children, and never needs a doctor, "although she pays into a club." No. 47: Was quite cured by an American goitre cure. No. 48: Patient attributes her improvement to pregnancy.

I will now briefly give you some examples from the private cases, and you will see that those which we have grouped among those that have done well have also really done well. No. 4, a severe case, although very nervous, has been very well and is still improving. No. 6: This case is of great interest, for the patient was very ill when I saw her, but now she does her household duties and goes for walks. No. 7: This patient also was very ill, but her pulse is now 80 and she is expecting her confinement daily. No. 8: Patient quite well. No. 9: Working as a schoolmistress. Nos. 10, 12, and 14: These patients are quite well. No. 15: Takes an average amount of exercise and is not debarred from any social functions. No. 17: Was very ill indeed. I have never seen greater exophthalmos, but that is now much less, and she can walk three miles and considers herself quite well. No. 18: Completely cured. No. 20: In seven months gained 28 lb. No. 21: A case of great interest. For seven years before I saw the patient she had had one lobe of the thyroid removed because of the disease. She got better for a time, but then the disease returned, and when I saw her she had most of the symptoms of exophthalmic goitre present in an extreme degree, and the remaining lobe of the gland was enormous, but after prolonged continuous rest she got quite well and can now walk to business and do a hard day's work. Her sister had the disease severely at the time the patient underwent the operation, but she was not operated upon; I saw her at the same time her sister was ill and she was well. Nos. 22, 23, 24, 25, and 26: These cases call for no comment. The patients are all in good health and apparently are cured. No. 29: Patient is in very good health and goes to dances. No. 30: This patient also says that she is in very good health and is busy from 7 A.M. to 10 P.M. No. 31: Patient has done very well. No. 34: Was very ill. She had a loud systolic murmur and great œdema of the legs, yet "she got practically well and went to New Zealand." No. 35: This case does not call for comment. No. 36: Patient can go for long walks. No. 39: A very severe case. Got quite well. No. 40: Got quite well. No. 41: This was a very severe acute case following influenza. The thyroid became much enlarged in 14 days, and when I saw the patient the restlessness and sleeplessness were so formidable and his pulse was so weak that it was thought he would die, yet within 12 months he was riding across country. No. 42: Got quite well. No. 44: Another severe case following influenza. Patient got quite well. No. 45: This case occurs in the list of those patients who died. The patient, however, recovered from her exophthalmic goitre, but some years later succumbed to diabetes. No. 48: Many years ago the patient had exophthalmic goitre and a fibroid of the uterus. When the fibroid shrank so did the thyroid. She got well (except for slight exophthalmos) of her exophthalmic goitre. I saw her for acute pneumonia, from which she recovered at the age of 67 without any return of the exophthalmic goitre. No. 49: Of interest as being a very severe case. No. 50: A very severe case, and when I first saw the patient 14 years ago she also had glycosuria. This disappeared in two years and had not returned since. Two years after she was first seen she could walk eight miles. She has for many years been perfectly well. No. 51: A very severe case. The exophthalmic goitre was attributed to influenza. A loud systolic murmur was audible. The patient had much œdema of the legs, but he got perfectly well. Nos. 55 and 56: These patients got quite well.

Most of those that are classified as having done moderately well are much better. Among the hospital cases No. 11 has had several attacks of mental derangement, but she is now considerably better and in a situation. No. 13: Patient says her health is fairly good. She was able to take a situation after leaving Guy's; then she married and has had two children. Nos. 16, 21, and 23: These patients are now much better. No. 26: Patient has a little breakdown occasionally but is much better on the whole. No. 36: Is now much better. No. 38: Has improved. Nos. 43, 44, 46, and 54: These patients evidently, from the words they use, are all considerably better. Of the private cases, No. 1 really seems to do well as regards her exophthalmic goitre. her chief trouble is arterio-sclerosis and granular kidneys. No. 2 underwent treatment irregularly but she is somewhat better. No. 5 has improved somewhat, but her case is complicated by the fact that she has a mild degree of Raynaud's disease. No. 11 is slowly improving. No. 28 is well except that she is highly nervous and easily excited. No. 32 is better but did not rest as advised. No. 37 is well of her

exophthalmic goitre, but has become an introspective neurasthenic invalid. No. 43 is much better and able to work, although she says she is not well. No. 54 is better and in fair health, but she was very ill and had to have the isthmus divided to relieve dyspnœa. It will be noticed that many of those who did only moderately well had some other disease besides exophthalmic goitre, or that they did not rest as they were told.

Two of the five cases that are grouped as not doing well are somewhat better and the other three refused treatment.

I think you will agree with me that these cases show that if we follow the after-histories of exophthalmic goitre they teach that the great majority of the cases do well. The private cases are seen by the table to have done better than the hospital cases, but really much better than the figures in the table show, for we have seen that the mortality is higher among the hospital than among the private cases. The private cases probably do better than the hospital cases because they are better able to rest.

I have classified my cases into (*a*) mild or average, (*b*) severe, and (*c*) very severe. The table of results shows that 26 hospital cases and 35 private cases had done well. Now of the hospital cases that had done well 18 were mild or average, 7 were severe, 1 very severe; and of the 35 private cases that have done well 18 were mild or average, 9 were severe, and 8 were very severe. These figures are of great interest, for they show that more severe and very severe cases get well in private than in hospital practice, thus quite confirming the conclusion we had previously reached that the outlook for sufferers from the disease is better in private than hospital practice.

TREATMENT.

The last part of the subject which I propose to discuss this evening is treatment. I have notes of 11 cases in which operations have been performed upon the thyroid gland with a view of benefiting exophthalmic goitre. Of these cases four patients died as an immediate result of the operation. The first, a woman aged 30, had the disease to an average degree, but was anxious for operation as the disfigurement prevented her from following her occupation as a barmaid. The right lobe of the thyroid was removed; the next day she became very excitable and nervous; the temperature rose to 103° F., the pulse became very fast, and she died. The second patient, a woman aged 19, had the right lobe and isthmus excised. She died on the day after operation. The third patient, a woman aged 29, had both superior thyroids tied. Later, under the attempt to tie the inferior thyroid, she suddenly died. The fourth case was that of a young woman who died on the operating table just as the operation of removing the left lobe was being completed. Seven patients who were operated upon did not die. The first had one lobe removed; she says (five years after the operation) that she is better. The second had the right lobe removed six years ago. Now she says that she is fairly well and is better for the operation. The third had the left lobe and isthmus removed. She says that she received great benefit, but that now she is "very bad at times." The fourth had the right lobe removed, and is now perfectly well. The fifth had the left lobe removed, and she reports herself as being better but by no means well. The sixth had the left lobe removed. She was then better for a time, but the right lobe began to enlarge enormously and she again had all the symptoms of exophthalmic goitre to an extreme degree. The seventh was better for the removal of the right lobe, but 16 years after the report is: "Distinctly better; no exophthalmos; some tachycardia and palpitation. Nervous symptoms much the same. Still odd mentally." Of these 11 cases 9 were of average severity and 2 were severe; of the latter 1 died and 1 recovered.

The above proportion of 4 deaths out of 11 cases operated on is about the same as that given by Dr. Hector W. G. Mackenzie for similar operations at St. Thomas's Hospital. It must be specially remembered that this serious mortality of nearly 40 per cent. is an immediate mortality, some of the patients even dying on the operation table, the others within 24 hours of the operation. If the patients are not operated on, we have seen that there is no immediate danger in the great majority of cases, that the disease frequently gets quite well, and that the actual deaths among those with exophthalmic goitre are not very many greater than among healthy females. A further argument against operation is, as we have seen, that in several cases the patient is not cured by the operation.

It must be admitted, however, that in the hands of some surgeons doing many operations on the thyroid the mortality has been gradually brought down very much lower than the figures I have given. But to get the best results after operation those patients are selected who have not had the disease long, who have no lesions of other organs, and who have no mental symptoms. We have seen that if we exclude patients who are so ill that they die while in the hospital (and therefore are quite unsuitable for operation) and follow for some years the patients who are discharged from the hospital and those who are seen in private practice, the actual deaths among sufferers from exophthalmic goitre ill enough to go into the hospital or seek a second opinion are 15 as against 8 expected among healthy females, although these patients afflicted with exophthalmic goitre include severe and very severe cases, those with other diseases in addition, and those with mental symptoms. As, on the other hand, the cases selected for operation are chosen mostly from among the mild cases and a few die as an immediate result of the operation, it hardly seems likely that operations on the thyroid can diminish greatly the deaths that might, if the patients were not operated upon, be expected among such sufferers from exophthalmic goitre as are likely to be selected as suitable for having operations performed on their thyroid. It is, however, quite possible that operation may hasten the cure; if so, the justification for doing it will be greater among wage-earners than among others.

It would be of great interest if a large series of cases which have been operated on could be traced for many years after the operation, so that we might learn more about the rapidity of the improvement, the duration of it, and the number of deaths as contrasted with those that might be expected among a similar number of healthy females. This is particularly important, for if the thyroid, which after operation consists of one lobe, shrinks, it may be that this leads after years to a mild degree of symptoms due to insufficiency of thyroid secretion. At any rate, the cases here recorded show that many patients, even those severely ill, recover and remain well for years without any operation; and that those who decline operation can hardly be considered unreasonable, especially in this country, where the mortality from such operations is higher than in some others. Further, we have to bear in mind that we may sometimes be in error in attributing benefit to an operation for exophthalmic goitre, for we have already seen that some patients recover without any treatment, and so some operated upon might have done well even if no operation had been performed.

We have just learned that in some patients there is a natural tendency for the disease to get well, and therefore it is difficult to come to a precise opinion about other treatments than the operative, but my belief is that the most important is absolute rest in bed for many weeks. During the daytime the bed should, whenever possible, be out of doors, and if the weather permits, the patient may be out of doors at night, at any rate she should sleep with her windows wide open. Recently a woman with exophthalmic goitre also had typhoid fever, and it was of great interest to notice how much her exophthalmic goitre improved during the progress of the typhoid fever, presumably because of the enforced rest in bed. If after the patient has rested in one place for a few weeks she is moved to some different scenery, say from inland to where she can see the sea, this appears to hasten recovery. When she begins to get up she must do so very gradually and must be very careful of undue exertion.

Next to rest, the most important feature of treatment is food; most patients with exophthalmic goitre are thin, and they will improve as they gain in weight; plain, simple food, and plenty of it, is needed. They must not be worried, the rest must be tranquil, they must be spared the housekeeping and other domestic duties, and it is because private patients can, so much better than others, rest quietly that they do better. It is extremely hazardous to try to estimate the value of drugs for this disease. Lately I have often given Moebius's anti-thyroid serum. It may be given in milk, five minim doses to begin with, but rapidly increased to 30 minims, three times a day. It has appeared to do good, and some patients think they are better for it, but certainly other patients do just as well without it. Its cost is an objection. Rodagen, a white powder consisting of the dried milk of goats whose

thyroid has been removed, is often prescribed; it probably acts, if it acts at all, in the same way as Moebius's serum. If the patients are very restless and excitable, it is of the utmost importance that they should be kept quiet, and in extreme cases hyoscine is certainly the best drug for this. I remember seeing a man, aged 30, who had acute exophthalmic goitre following influenza; he had great tremor, was extremely restless and sleepless, and so ill that it was thought he would die. After a subcutaneous injection of hyoscine, 1/100 grain, he slept for the first time for a long while, and ultimately got quite well. For less severe cases paraldehyde is very useful, and for still less severe cases I usually prescribe bromides. If there is much tachycardia it seems only natural to give digitalis, and sometimes the patient seems better for it. The anæmia from which patients suffer usually passes away as they improve.

(Readers who wish for the details of each of the cases here mentioned will find them in the *Quarterly Journal of Medicine*, Vol. iv., No. 13.)

A Post-Graduate Clinic

ON

RECURRING ARTERIAL HYPERTONUS IN GRANULAR KIDNEY AND IN MIGRAINE.

Delivered in the Royal Infirmary, Edinburgh, on Sept. 6th, 1910,

BY WILLIAM RUSSELL, M.D., F.R.C.P. EDIN.,

PHYSICIAN AND LECTURER ON CLINICAL MEDICINE, ROYAL INFIRMARY, EDINBURGH.

GENTLEMEN,—There are two patients in the adjoining ward whom you will have the opportunity of seeing and examining for yourselves after I have given you an account of the clinical phenomena which have been noted in them during the time they have been in the ward.

GRANULAR KIDNEY.

CASE 1.—The patient is 52 years of age. She has had a checkered life, has been in this infirmary and in the workhouse hospital on more than one occasion for various ailments, and she frankly acknowledges to having been "fond of a good big dram." The details of such a life do not require to be dwelt upon; the results of it at 52 years of age are illustrative of a large group of cases, not all, however, presenting a personal and social history of hard work, poverty, ill-treatment, and bad habits. The patient was admitted on June 10th, 1910. She stated that for some weeks she had been breathless, especially on going upstairs, while latterly it was continuous; she also suffered from attacks of dizziness; her legs also at times became weak and shaky, and she had difficulty with her speech at times—she stammered and could not get the words out. She sought advice at the Cowgate Dispensary, was recommended to the infirmary, and was admitted under my care.

On admission the pulse was 80, the respirations were 24, the temperature was 97° F., and the brachial pressure was 295 mm. Hg. She was kept in bed, put on milk diet, and was given a dose of Henry's solution at night. The radial artery was thickened, but did not give the impression of anything like the pressure given by the brachial. The heart dulness at the apex was in the nipple line; the sounds were clear and slapping, and there was no murmur. The lungs were emphysematous but otherwise normal. The urine had a specific gravity of 1017, and showed a faint trace of albumin. The blood count and the amount of hæmoglobin were normal. The bowels moved once or twice daily. By the 14th the pressure had fallen to 185 mm. Hg. She was then given 5 grains of potassium iodide three times a day. On the 18th the pressure had fallen to 165 mm. and she was allowed light diet, which includes chicken and fish. From that date to July 2nd the pressure varied from 165 to 210 mm.—the level being somewhat higher after the increase in her diet than before that. On the forenoon of July 4th she was not so well, and, when I saw her, her face was flushed, she was propped up in bed with pillows, she looked dazed, and when spoken to could not articulate; the pulse was rather over 100, the respirations were 24 and laboured, and the brachial pressure had risen to 268 mm. She was given erythrol at once, and at night had a dose of mannitol. She rapidly regained her ordinary condition, had a good night, and next morning the pressure had fallen to 190 mm., and she felt in her usual health. On August 12th, with her pressure only at 202 mm., she complained of headache, a tingling sensation in the right limbs, right side of the trunk, and in the corresponding side of the tongue. These sensations continued, and she was given erythrol. On the 14th the pressure was 186 mm. On the 30th the patient was noted to be particularly well in the morning, but at about 6 P.M. she became restless; at 7.30 she complained of violent pain in the head, was breathless, and had difficulty in articulation; at 8.15 the pressure was 258 mm. and she was given erythrol; and at 9.30 the pressure had fallen to 207 mm., and as she was drowsy she was not disturbed again, and she soon fell asleep. The following morning the pressure had fallen to 175 mm., and since then she has been in her usual condition, the pressure keeping about 200 mm.

The course of the pressure may be tabulated thus:—

June 10th	295 mm. Hg.	August 14th	186 mm. Hg
,, 11th	230 ,,	,, 30th (8.15 P.M.)	258 ,,
,, 18th to July 2nd	165–210 ,,	,, ,, (9.30 P.M.)	207 ,,
July 4th	268 ,,	,, 31st	175–185 ,,
,, 5th	190 ,,	Sept. 1st	204–207 ,,
August 12th	202 ,,	,, 3rd	208–212 ,,

June 10th, July 4th, and August 12th and 30th were the dates of the attacks.

This patient is suffering from the effects of granular kidney and extensive arterial change, and I bring her case before you to illustrate the clinical lessons such a case supplies, and to impress upon you some points which it is of the first importance for our patients that we should understand the true significance of and be able to treat intelligently, and then, happily, successfully up to a certain point.

You will note that this woman on admission had a vessel pressure of 295 mm. Hg, one of the highest pressures I have had in this ward, and that rest in bed, the administration of a saline purge, milk diet, and later 5 grains of potassium iodide thrice daily brought the pressure down from 100 to 130 mm. During the period she has been in hospital she has sometimes shown symptoms which are classed as uræmic, such as restlessness, incoherence, dyspnœa; at other times, symptoms that are regarded as premonitory of cerebral hæmorrhage or cerebral softening from local anæmia or thrombosis, such as tingling in one-half of the body, confusion of thought, difficulty in articulation, even loss of articulate speech. She has had several minor manifestations in one or other of those directions; but she has had two or three graver attacks, in the first of which I was fortunate enough to see her and at once to recognise its nature. In all these attacks I ask your attention to the fact that the pressure showed a great rise—a rise which would doubtless have risen still higher had it not been arrested by therapeutic interposition. With such interposition, however, the pressure fell, as on July 4th, from 268 to 190, and on August 30th from 258 to 175 mm. With the fall of pressure all the urgently alarming symptoms disappeared; in fact, the arrest of its upward movement, and a fall even of 15 or 20 mm. brought visible relief to the symptoms, and this was effected in a remarkably short space of time. The association of a marked rise in hæmomanometer reading with such symptoms as I have indicated is in my experience always to be noted.

Neither the ordinary pressure nor the rise in pressure in these cases can always be estimated correctly by the finger on the radial artery. None of you would guess from this patient's radial artery that the pressure would be as high as it is; indeed, those of you who study blood pressure by the finger will think that it is even lower than normal. I entirely agree with those of you who may think so. The finger, I hold, is the only means by which you can estimate true blood pressure. True blood pressure to the clinician means the power of the left ventricle, and nothing else, as that can be estimated by the finger on an artery. The hæmomanometer reading, on the other hand, is only in part the result of blood pressure. The patient we are considering has

a variation in her hæmomanometer reading from 295 to 165—a margin of 130 mm., and certain eminent persons would ask us to believe that this is the margin of power in this woman's left ventricle, a margin which no healthy man in this room possesses. But I do not propose to argue this point: I have done that in other places. I merely state that this great margin of pressure, that these great variations in pressure, indicate to us the condition of the arterial wall—the degree of hypertonic contraction, or of relaxation of it. The armlet being applied to the upper arm gives us the condition of the brachial artery, which every now and again differs greatly from the bit of radial artery to be felt at the wrist. This observation as to the state of the brachial artery, added to your examination of the radial artery and pulse, you will find a great help in estimating correctly the state of the circulation in your patients.

Let me repeat that in this patient we had, and will have again, symptoms of uræmia, and symptoms which presage cerebral softening or hæmorrhage; that when these threatenings are present the hæmomanometer reading is found to have risen many millimetres. My contention is that the raised reading is due to hypertonic contraction of the artery from which the reading is taken. The symptoms are associated definitely with this phenomenon, for the moment you arrest the constrictive action the symptoms begin to disappear, and altogether disappear with the cessation of the hypertonus and the consequent fall in the hæmomanometer reading.

To you as graduates in medicine I need not labour to prove the great value, therefore, of this instrument, if you use it aright and interpret its readings correctly. I shall only ask you to realise what the phenomena are which are commonly recognised as presaging paralysis, hemiplegia being the commonest, associated or not with aphasia. Very many of these cases are preceded for days or for longer periods by recurring sensations of numbness or tingling, by temporary slight loss of power in a hand, an arm, a leg, difficulty in articulation, temporary loss of speech, feeling of mental confusion, temporary loss of memory, and so on. All these you will find associated with arterial hypertonus and a high hæmomanometer reading. The nervous phenomena can only be explained by the participation of the vessels in varying parts of the brain in a constriction in which the whole systemic circulation is affected. These local angiospasms in the brain lead to anæmia of the areas involved, the clinical phenomena being referrable to the areas so affected. The angiospasm in brain areas favours thrombosis, and its consequent deplorable brain softening, or leads to hæmorrhage on the heart side of the region of spasm.

Now I unhesitatingly assert that if these phenomena are duly observed, correctly correlated and interpreted, you have it in your power in many instances to save your patients from disaster, preventing their being deprived of the power of locomotion, of speech, of mental power, perhaps for years longer than would otherwise be the case.

The patient who is the text of these remarks is but one of many similar cases I could describe to you. I am glad that a case of the kind happens to be in the ward at present, so that you may see the case and note the difference between the radial pulse and the high pressure required to obliterate the brachial artery, and realise that this simple instrument, the hæmomanometer, is really a great help in your every-day medical work if you use it as a guide to the state of the vessel wall more than as a guide to blood pressure, although in other classes of cases it can even help you in judging of that.

MIGRAINE.

CASE 2.—The second case to which I ask your attention is also of interest, although not of such urgent importance as the preceding one. The patient, a woman aged 49 years, was sent to me in May, 1909, by Dr. W. C. McEwan of Prestonpans as she was suffering from migraine, having an attack almost every week, the attack lasting three or four days. At that time the radial artery was small and wiry and the brachial pressure 150 mm. Hg. The bowels were constipated, the tongue coated, the breath offensive, and there was a trace of albumin in the urine, which also showed much indican. I advised that she should have a laxative pill nightly of cascara, belladonna, and nux vomica, and iodide of potassium thrice daily. Under this treatment she improved, but as the attacks returned she was again sent to see me and was admitted into the adjoining ward on August 12th, 1910. On admission the pressure was 205 mm. She was treated with enemata to unload the bowel and got a colocynth and hyoscymus pill to keep the bowels moving. Under this treatment and rest in bed the pressure fell and kept between 164 and 172 mm. On August 21st the pressure was 164 mm. On the 23rd, in the evening, she complained of headache, vomited twice, and she knew that one of her attacks had begun. She vomited several times during the night. On the 24th her condition was unchanged, she vomited twice, and the pressure was 192 mm. On the 25th her condition still remained the same, and the pressure was 194 mm., when she was given a quarter of a grain of erythrol, the hour being 12.25 P.M.; by 12.55 the pressure had fallen to 142 mm.; by 1.50 it had risen to 168 mm., and by 7.45 to 179 mm. On this date (the 25th) she vomited six times between 1.30 P.M. and 9 o'clock, and as her symptoms were not at all relieved by the fall of pressure produced by the erythrol the drug was not repeated. On the 26th the headache was much less and the vomiting had stopped. The attack had lasted part of three days. On the 27th there was neither headache nor sickness, and the pressure had fallen to 138. On Sept. 1st the pressure was reported as rising steadily and had reached 172. The patient thought she was to have another attack, as she had a feeling of fulness in the right arm, a symptom she had noticed previously as indicating the approach of an attack. On the 2nd, in the morning, headache began, and at 10.30 A.M., when I saw her, the pressure was 203. I ordered 10 grains of phenacetin every hour for three times. At 1 P.M., the pressure being still 203 mm., she was given the first dose; at 1.45 the pressure was 187 mm. and the headache was slightly relieved; at 2.30 she was given the second dose, and at 2.45 the pressure was 184 mm. and the headache continued relieved; at 3.30 she was given the third dose, and at 4 o'clock the headache was distinctly better and the pressure was 178 mm.; at 7 P.M. the headache was much better and the pressure was 178 mm. There was no vomiting and the patient had a good night, sleeping soundly. The following morning, Sept. 3rd, she expressed herself as feeling quite well and the pressure had fallen to 158 mm. She has remained well down to the present.

The course of the hæmomanometer readings may be tabulated thus:—

	May, 1909	150 mm. Hg.			
	August 12th, 1910...	205	,,		
	,, 13th-20th ,, ...	198-165	,,		
	,, 21st ,, ...	164	,,		
	,, 24th ,, ...	192	,,		
Attack	,, 25th ,, ...	194	,, ...	12.25 P.M., erythrol.	
		142	,, ...	12.55 ,,	
		168	,, ...	1.50 ,,	
		179	,, ...	7.45 ,,	
	,, 27th ,, ...	138	,,		
	Sept. 1st ,, ...	172	,,		
Attack	,, 2nd ,, ...	203	,, ...	10.30 A.M.	
		203	,, ...	1.0 P.M., phenacetin.	
		187	,, ...	1.45 ,,	
		184	,, ...	2.30 ,, phenacetin.	
		184	,, ...	2.45 ,,	
			,, ...	3.30 ,, phenacetin.	
		178	,, ...	4.0 ,,	
	,, 3rd ,, ...	158	,, ...	morning.	

August 24th and Sept. 1st are the dates of two attacks—the first treated with erythrol and the second with phenacetin.

This case raises various questions which cannot at present be discussed. Some of these questions are: Are the attacks primarily of nervous origin, and if so are they neurasthenic or epileptoid? Are they nervous manifestations of early cirrhotic kidney? Or are they the result of a primary auto-intoxication due to some error in metabolism, or to the retention of some product not being regularly excreted? We are engaged in the investigation of the urine with a view to the possible determination of this last question, but meanwhile we have not got far enough to entitle me to speak about it. I bring the case before you as showing the interest that is attached to hæmomanometer observations, and that the instrument is well deserving of a place in ordinary medical work. In this patient I have shown that her attacks are associated with a marked rise in hæmomanometer readings, but it would appear that the mere reduction of pressure, as in the attack beginning on August 23rd, did not modify the course of the attack in any way. It may be that had the erythrol been

given sooner and been persevered with the result might have been different. However that may be, the difference between that attack and the attack on Sept. 2nd, which was at once treated with phenacetin, is very striking; in it the symptoms were promptly arrested and aborted, and along with that there was in three hours a fall in pressure of 25 mm. By the following morning a fall of 45 mm. had occurred, accompanied by the relief of all the symptoms. In this attack headache was arrested and vomiting was prevented by the administration of phenacetin, the drug above all others that arrests migraine.

Since the above was written this patient has left hospital. She left on Oct. 15th, having passed nearly a month without an attack, although in that time she had two threatenings of attacks, which have been designated in the subjoined table "abortive attacks." These abortive attacks were characterised by a feeling of drowsiness and by urine changes as indicated below. The examinations of the urine which were being carried out as mentioned above have been completed. They are given below and form an interesting contribution to the question of chloride excretion in migraine; they show a relationship between the migrainous attack, the occurrence of polyuria, and the discharge of a large quantity of chloride followed by a big drop in chloride excretion.

Amount of Urine and Chlorides Excreted in relation to Attacks of Migraine in Case 2.

* Containing 6·5 grammes chloride.

The patient left the hospital on Oct. 15th, not having had any more attacks.

I have to express my indebtedness to my residents, Dr. R. W. Lang Todd, Dr. T. Welsh, and Dr. A. L. Taylor, for their watchful interest in these cases.

PROPOSED NEW HOSPITAL FOR AXMINSTER.

At the annual meeting of the subscribers of the Axminster (Devon) Cottage Hospital, which was held on Nov. 15th, Mr. W. Langran, honorary surgeon to the institution, stated that the hospital was now out of date, and as there was a substantial reserve fund he proposed that a new building fitted up to modern requirements should be erected. After some discussion it was decided to take steps for the erection of a new hospital.

An Address

ON THE

DIAGNOSIS AND TREATMENT OF CYSTIC DISEASE OF THE BREAST.

Delivered before the Harveian Society of London on Oct. 27th, 1910,

BY D'ARCY POWER, F.R.C.S. ENG.,

SURGEON TO, AND LECTURER ON SURGERY AT, ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—When you invited me to select a subject for discussion here to-night I turned over in my mind the various cases which have come under my notice as a surgeon to one of the large teaching hospitals in London. I quickly arrived at the conclusion that cystic tumours of the breast often gave me trouble both to diagnose and to treat, and I was vain enough to think that what proved difficult to me might have proved equally difficult to others. I have therefore chosen to bring this subject before you in the hope of obtaining a full discussion. Such cases are not rare, and it is the essence of a good discussion that it should be upon a topic with which everyone is familiar.

CLASSIFICATION.

The classification of cystic disease of the breast is chaotic, and I would therefore submit the following classification for your consideration and approval, not because I believe it to be perfect but in the hope of obtaining some kind of order:—

(A) *Non-inflammatory.*		
(*a*) Innocent.	(I.) Adenoma.	(i.) Ducts.
		(ii.) Acini.
	(II.) Fibroma.	(i.) Pericanalicular.
		(ii.) Intracanalicular.
(*b*) Malignant.	(I.) Carcinoma.	(i.) Duct papilloma.
		(ii.) Duct carcinoma.
	(II.) Sarcoma.	(i.) Cystic.
		(ii.) Degenerating.
(B) *Inflammatory.*		
	(I.) Galactocele.	
	(II.) Mastitis.	(i.) Cyst simple and single.
		(ii.) Cysts multiple.
(C) *Congenital.*	Lymphangioma.	
(D) *Parasitic.*	Hydatid.	

(A) NON-INFLAMMATORY CYSTS.

(*a*) *Innocent cystic tumours.*—Everyone recognises the existence of cystic adenomata as one of the commoner forms of innocent tumour occurring in the breast. The actual structure differs in different tumours. It is sometimes, but rarely, pure glandular tissue of an imperfect type held together by a little areolar tissue, the glandular tissue being sometimes chiefly acinous and in other cases chiefly tubular. Much more frequently the glandular elements are scattered in a stroma of fibrous connective tissue and the tumour is then called a cystic fibro-adenoma. Here are two examples of such a tumour, the first of which is almost typical:—

CASE 1.—An unmarried woman, aged 21 years, had accidentally noticed a lump in her breast six months previously. It was small at first but had doubled in size before she sought advice. Her breast ached a little, but never enough to be troublesome. Examination showed that both breast and nipple looked natural. The hand laid flat upon the left breast felt a rounded swelling which measured about an inch in diameter. The swelling was hard and nodular, well defined, and painless. It floated, that is to say it moved freely, not only beneath the skin and upon the pectoral fascia, but in the substance of the breast itself. A small incision radiating from the nipple allowed the tumour to be removed with the greatest ease. The tumour appeared to the naked eye as an irregular mass of glandular tissue from the edges of which projected small cysts filled with transparent yellowish fluid. Microscopically it was a fibro-adenoma consisting of glandular acini in a stroma of fibrous tissue.

CASE 2.—A married woman, aged 30 years, had first noticed a lump in her left breast seven months previously, her attention being drawn to it by accident. The swelling had increased a little in size, but she came for advice because it was beginning to be painful after she had used her arm. Examination of the breast showed that it contained a rounded swelling measuring half an inch across and divided into two lobules. The swelling was freely moveable in the breast, and there was no enlargement either of the axillary or the supraclavicular glands. The tumour was removed by simple incision and proved to be a cystic fibro-adenoma.

The secret of removing these tumours lies in making the assistant press them up closely beneath the skin and then cutting down upon them until the capsule of the adenoma is reached. I have sometimes seen them very badly removed by those who have failed to appreciate the necessity for cutting cleanly through the breast tissue before any attempt is made to enucleate the tumour.

It is not necessary to remove every adenoma of the breast, but it is better to do so in those who are unable to bear with equanimity the thought of having a tumour in the breast, in those who have a strong family history of cancer, when the tumour grows rapidly and when it is really painful.

Cystic fibroma.—Cystic fibroma of the breast occurs in two forms, and the name of Sir Benjamin Brodie's disease of the breast is sometimes given to it. A more intimate knowledge of the pathology and microscopical structure has enabled us to subdivide Brodie's disease into an innocent form—cystic fibroma—and a malignant form—cystic sarcoma. Cystic fibroma of the breast may be further subdivided into pericanalicular fibroma and intracanalicular fibroma. Both forms are characterised by an overgrowth of connective tissue starting either in the stroma round the ducts and acini—the pericanalicular form—or in the subepithelial tissue of the ducts themselves—the intracanalicular variety. Both tumours are associated with the formation of numerous cysts which are filled at first with serous fluid. The cysts, therefore, are due in all probability to obstruction of the glandular tissue, although in some cases there is microscopical evidence that the glandular epithelium has itself undergone cystic degeneration. The cyst wall in the pericanalicular form is often invaginated by the new growth of fibrous tissue until the cyst becomes a mere slit, and the tumour appears to be solid on section until a probe is passed into the slits, when the invaginating growth can be turned out and the cyst demonstrated.

In the intracanalicular form the cyst remains obvious and the growth sprouts into it in the form of a duct papilloma.

CASE 3.—This is a section through a large and lobulated pericanalicular fibroma of the breast. The cysts are very large and are filled with a firm growth. It will be noticed that, although the growth fills the cysts in such a manner as to make the section appear solid, it is in each case a mere approximation of the cyst wall and it can readily be turned out to show its independence of the cysts. Microscopically the tumour is a true pericanalicular fibroma. The breast was removed from a married woman, aged 52 years, who first noticed a small lump in her breast ten years before amputation was performed. The tumour began to grow two years after it was first noticed, but during the last three years the rate of growth had increased rapidly.

CASE 4.—The following is a good instance of the intracanalicular cystic fibroma, which was recently under my observation. An unmarried lady, aged 55 years, came to see me in August, 1909, saying that six weeks ago she had first noticed a little blood-stained discharge coming from her left nipple. Three weeks later the discharge, which was clear and blood-stained at first, became thick and made her linen stiff when it dried. Careful examination showed the breast to be healthy except at one spot just to the outer side of the nipple where there was a slightly thickened patch which was not tender on pressure. There was no enlargement of the axillary glands. I made a diagnosis of duct papilloma, but rather dissuaded the patient from any operation as she had lately suffered from several attacks of angina pectoris. I told her to come and see me again in two months' time unless any marked change took place in the interval. She returned on Oct. 8th saying that the discharge had neither increased in quantity nor altered in quality, though my examination of the breast at the previous visit had been followed for a few days by a little more bleeding than usual. I again temporised, but on Oct. 25th the breast suddenly increased in size without any apparent cause. It became red and tender, so I determined to remove it at all risks. I amputated the breast on the 27th, and subsequent examination showed a papillomatous growth of about the size of a pea projecting into a cyst filled with blood-stained and purulent fluid. The cyst was surrounded by an extensive area of thickened tissue. The axillary glands were unaffected.

The following report was afterwards received from the Clinical Research Association: "This is an inflammatory lesion of the breast with much induration, as well as some recent and acute changes round the ducts. We may conclude, therefore, that it is a simple chronic infection as there is no evidence of tubercle. There is a fair-sized duct papilloma in one place, but it is well encapsuled and there is no evidence of malignant growth."

CASE 5.—A married woman, aged 45 years, first noticed a lump in her breast ten years ago. It was then as large as a pea, and there was an occasional discharge of a few drops of yellowish but inoffensive fluid. The swelling gradually increased in size, but during the last six years there had been no discharge. The increase in size was attended with pain. The patient had been married for 25 years, but had neither had children nor miscarriages. Examination showed a rounded and slightly lobulated swelling occupying the inner half of the left breast. The skin over the swelling was freely moveable and was not altered in character, except that it contained a single enlarged vein. The tumour was not attached either to the skin or to the deeper tissues. It gave the sensation of a tense fluid swelling. The right breast was normal. The swelling was removed on May 3rd, 1910, and the patient left the hospital on May 19th with the wound soundly healed.

The tumour is preserved in the Museum of St. Bartholomew's Hospital (No. 3146*b*) with the following description: "Part of a female breast showing a cystic duct papilloma with intracystic growths. A piece of skin, including part of the nipple, forms the anterior aspect of the specimen. Beneath it is a cyst measuring about half an inch in diameter. The cyst is thin-walled and was not adherent to the skin. Its inner aspect is roughened by a granular deposit of blood-stained débris. Two intracystic papillary growths are seen at one extremity of the cyst, to the wall of which they are attached by delicate pedicles. The cyst contained bloody fluid when it was fresh. Microscopical examination shows the intracystic growth to be a duct papilloma."

The connective tissue stroma in the intracanalicular forms of cystic adenoma may itself undergo secondary changes, as happened in the following case:—

CASE 6.—A married woman, aged 45 years, was admitted under my care at St. Bartholomew's Hospital on May 29th, 1910, complaining of a painful tumour in the left breast. The swelling had been noticed for the last 20 months. It was painless at first, but five months before she sought advice it began to grow and was painful. There was no history of any injury. Examination of the breast showed a diffuse and rounded prominence over the left nipple which proved on palpation to be a tense and lobulated swelling which was not attached either to the skin or to the underlying tissues. There was a small painless swelling in the left axilla which had only been noticed for three days. The breast was explored on May 20th and a thin-walled cyst filled with brownish fluid was dissected out. Subsequent examination showed that it contained a vesicular mass which seemed to be of a colloid nature.

The specimen was sent to the museum where it is preserved (No. 3146*k*) with the following description: "A cystic papilliferous fibro-adenoma. The tumour is globular and multilocular, measuring 2 inches in diameter. A quantity of gelatinous papillary growth springs from the inner wall of the main cavity of the cyst, which it fills completely. Microscopical examination shows that the gelatinous outgrowths are composed of myxomatous tissue covered by flattened epithelium. The cyst wall is fibrous and contains spaces lined by epithelium similar to that which covers the papillary growths."

(*b*) *Malignant cystic tumours.*—Malignant cystic disease attacks the same parts of the breast as cystic fibroma. It occurs, therefore, in the two forms of cystic sarcoma and duct cancer, the sarcoma corresponding with pericanalicular cystic fibroma, duct cancer being the correlative of the intracanalicular non-malignant forms.

Cystic sarcoma of the breast is at first a well-circumscribed swelling which grows in the same manner as sarcoma in other parts of the body. The cysts, however, are constituent parts of the growth and are not mere degeneration products due to retrograde changes in the newly formed sarcomatous tissue. The cases are not very common, but here is a good example which came under my observation when I was acting as house surgeon to Sir William Savory, who spoke of it by the name under which it was known to Sir Benjamin Brodie himself as a sero-cystic sarcoma.

CASE 7.—A married woman, aged 37 years, the mother of nine children and four months pregnant, was admitted into Lucas Ward at St. Bartholomew's Hospital on March 12th, 1883, with a tumour rather larger than an egg in the upper part of the left breast. The swelling had been first noticed three months previously and it was then the size of a walnut. On examination it was found to occupy the upper segment of the breast near the periphery. It was moveable and bossed; fluctuation could be felt distinctly. The swelling did not extend to the nipple, but was connected with it by indurated bands. There was no serous discharge from the nipple and there were no enlarged axillary glands. One of the fluctuating parts of the tumour was punctured with a grooved needle on March 13th and about two ounces of clear fluid escaped. An incision was made into the tumour on March 24th and clear fluid again escaped. The incision never closed and there was a constant oozing of serous fluid from it. The patient left the hospital at her own wish on April 13th and was readmitted on May 15th, saying that she had suffered much pain in her breast, which was always wet, and that something had grown out of the wound. Examination showed that the left breast was much larger than before, the skin over it was tense and red, whilst the whole gland was harder than natural. A large fungating mass was growing from the site of the incision and there was a constant oozing discharge of clear serous fluid. The patient otherwise was in excellent health. The breast was removed on May 19th and the patient left the hospital with the wound soundly healed on June 8th. Subsequent examination showed that the breast contained a cyst as large as an orange embedded in a mass of sarcomatous tissue.

These cystic sarcomata of the breast must not be confused with sarcomata in which cysts are produced as a result of degenerative changes. The following is a good example of a case of degenerating sarcoma:—

CASE 8.—A married woman, aged 51 years, was admitted under my care on June 2nd, 1907, complaining of a painful lump in her left breast.

The swelling had been noticed for eight weeks, and during this time it had increased from the size of a Barcelona nut to that of an egg. Examination showed a tumour as large as a hen's egg in the upper quadrant of the left breast. The nipple was not retracted and there were no enlarged glands in the axilla or above the clavicle. The patient was extremely unwilling to have the breast removed, and I was only allowed to operate upon condition that the tumour was removed locally, whatever its nature. I cut into the breast, therefore, and removed the mass, which seemed to be well encapsuled, and with it I removed a wide margin of healthy tissue. Subsequent examination of the tumour showed it to be a spindle-celled sarcoma with no evidence of any cystic formation.

The patient returned to the hospital in June, 1908, saying that she had noticed a lump in the breast beneath the scar in the previous April, ten months after the operation. Examination showed the recurrent mass to be a hard and fairly well-defined swelling, measuring 4 inches by 2 inches. It was moveable, and the skin over it was not adherent. There were one or two enlarged glands in the axilla. The whole breast was removed with the contents of the axilla and the superficial fibres of the pectoralis major. The growth in the breast proved to be so well encapsuled that it could be dissected out of the breast tissue with comparative ease. It was lobulated, and in many cases it was excavated into ragged cavities which contained degenerating new growth. Microscopic examination showed the growth to be a spindle-celled sarcoma.

Duct carcinoma is not very uncommon. It is always cystic, the cysts being either simple or multilocular. The following case is an example of the multilocular cystic form:—

CASE 9.—A woman, aged 68 years, was admitted into St. Bartholomew's Hospital under my care complaining of a lump in her left breast. She had first noticed the swelling 18 months previously, when it was as large as a pigeon's egg. It grew slowly but painlessly. There had never been any discharge from the nipple. Examination showed a large, irregular, and fairly well-defined swelling in the left breast to the outer side of the nipple. It was not tender and it was not fixed to the deeper structures. It moved freely with, but not in, the breast. The patient had been married 48 years and was the mother of seven children. She had bruised her left breast very severely 30 years previously by falling against a door. The breast was removed on Feb. 22nd, 1910, and the patient left the hospital on March 10th.

The specimen was sent to the museum where it is preserved (No. 3146*a*), with the following description: "Part of a female breast containing a multilocular cystic duct carcinoma. Embedded in the adipose tissue of the breast is a globular tumour measuring about two inches in diameter. It lies close beneath the skin, which is nowhere adherent to it. The tumour is encapsuled for the most part, but here and there it cannot be defined from the surrounding fat. The tumour is partly solid and partly cystic. The cut surface shows the interior of the largest cyst which, like the smaller ones seen upon the reverse side of the preparation, contained a bloody fluid. The solid parts of the tumour consist of a number of rounded ingrowths from the periphery. Microscopical examination shows the growth to be a duct cancer."

(B) INFLAMMATORY CYSTS.

Cystic disease of the breast connected more or less directly with inflammatory changes is of greater diagnostic interest and may present greater difficulties in treatment than the non-inflammatory forms which have just been discussed. Foremost amongst these cysts, and in many ways the simplest, is galactocele. A galactocele is generally the result of inflammatory changes occurring in the breasts of married women. The following case shows that it may be produced as a result of injury to a virgin breast:—

CASE 10.—An unmarried governess, aged 31 years, was sent to see me because she had been complaining of pain and swelling in her breast. She said that five months previously she had been struck upon the breast, a bruise had resulted from the blow, and the breast had become tender. Examination showed that she had a small and freely moveable swelling in the lower and outer quadrant of the right breast. The tumour was in the breast substance and moved when the breast moved, but it was not independent of the mammary tissue and did not give the sensation of floating which is so often felt in the cystic adenomata. The swelling was slightly tender. There was no discharge from the nipple and there was a single enlarged gland in the axilla. The history of the case and the bruising which had followed the injury led me to make a diagnosis of a circumscribed hæmatoma in the glandular tissue. I incised the swelling under a general anæsthetic and found a cyst containing a milky fluid. The swelling therefore was a galactocele. The interior of the cyst was swabbed out with a solution of zinc chloride, 40 grains to the ounce. A drainage-tube was left in for 24 hours and the small incision was sutured. The wound healed by first intention.

Chronic mastitis leads to the formation of a most interesting group of cystic tumours. The cyst in these cases may be single and simple or the whole gland may present the appearance of a sponge when it is examined after removal. The following case is a good example of a single and simple cyst:—

CASE 11.—A married woman, aged 43 years, was admitted into St. Bartholomew's Hospital under my care complaining that she had a lump in her right breast. Twelve months previously she had noticed that her right breast was harder than the left, but she took no particular notice of the fact until Oct. 2nd, 1908, when the breast became more swollen after two days' hard work. She had never suffered any pain. Eighteen months ago she had fallen heavily against a bedpost and had struck her breast. Examination showed a tense lump limited to the upper half of the breast; it was freely moveable upon the pectoralis major and was definitely circumscribed. Careful manipulation yielded a sense of fluctuation. It was not tender, the skin over it was not adherent, and there was no retraction of the nipple. Two or three enlarged glands could be felt in the axilla, and the patient said that she had lost weight. There were some grounds, therefore, for thinking that she might be suffering from a scirrhus. I made a vertical incision into the swelling on Nov. 2nd and clear serous fluid squirted out. The incision was enlarged and a simple cyst was removed. The cyst wall was thickened, fibrous, and firmly adherent to the glandular tissue surrounding it. The cyst measured 1½ inches in diameter when it was distended. The patient left the hospital on Nov. 11th.

CASE 12.—A married woman, aged 48 years, was admitted into St. Bartholomew's Hospital under my care with a lump in her left breast. She said that she had first noticed it nine weeks previously when her attention was directed to it by pain. It had increased steadily in size. She was the mother of nine children; at various times and repeatedly she had been struck on the chest and her nipple had often been chapped. Examination showed the existence of a very hard and craggy lump in the lower and outer quadrant of the left breast. It was about as large as a hen's egg and was freely moveable. There were a few enlarged glands in the left axilla. The right breast and its axillary lymphatic glands were natural. The history of the injury and the fact that she had felt pain in the breast led me to incise the swelling, which proved to be a cyst filled with clear yellowish fluid under considerable pressure. Frozen sections of the indurated tissue round the cyst were made at the time of the operation. They showed that the thickening was due to chronic inflammation. The wound healed by first intention and the patient was discharged on August 14th, ten days after the operation.

CASE 13.—A very nervous married lady, aged 49 years, was sent to see me on account of a painless tumour which she had noticed for the previous three weeks in her right breast. The swelling only occupied a part of the breast. It felt densely hard and there was a slight irregularity at the lower and outer part of its circumference. There was a single enlarged gland high up in the axilla. The patient said that many years ago she had suffered from an inflammation of the breast when she was suckling. I had no doubt in my own mind that she was suffering from a scirrhous carcinoma, and I advised her to go to a nursing home as soon as possible with a view to removal of the breast, if after incision the tumour was found to be solid. At the same time I told her doctor that it would be advisable to cut into the swelling before the breast was removed because she had previously suffered from mastitis and because the axillary gland seemed to be rather softer than is usually the case in cancer. She was persuaded by her friends to see another surgeon before following my advice. He put a trocar and cannula into the tumour and drew off two or three ounces of clear fluid. The swelling no doubt was a simple cyst originating in the ducts or acini of the breast tissue. The cyst had become enlarged as a result of long-standing inflammatory changes brought into prominence by the retrograde processes taking place in the breast at the menopause. I ought, of course, to have recognised the cyst by its elasticity as well as by the slight irregularity of the circumference which pointed to a patch of localised mastitis such as is not common in cases of cancer. But I should have discovered the cyst at the time of the operation without removing the breast and perhaps in a safer way than was actually done, although it seemed much more satisfactory to the patient to have it tapped there and then and thus to be relieved of the swelling at once. The moral of the case is not to give too decided a prognosis in cases of doubtful mammary tumour, for a cyst may simulate very closely a solid tumour.

There is another group of cases in which a chronic inflammation of the breast is associated with a formation of cysts which may be single but are much more frequently multiple. The following case is a good example of the type and is unusually complete as I had the opportunity of watching it for a long time:—

CASE 14.—A female patient, aged 34 years, and unmarried, came to me on March 11th, 1906, complaining of a painful swelling in the right breast. She said that she had first noticed "something wrong" with her right breast in December, 1904, and that in April, 1905, the breast contained a definite swelling of about the size of a peanut. The swelling remained stationary in size until November, 1905, when it began to grow. A month later it was painful for the first time. There was no loss of weight. She was a healthy woman when I saw her in March, 1906, and her breast looked natural. Examination showed that there was a hard mass in the upper and inner quadrant which measured an inch and a half in length by an inch in breadth. The mass was slightly tender and there was no enlargement of the axillary glands. The swelling was definitely limited in outline and was freely moveable in the breast tissue as well as upon the underlying structures. It did not fluctuate. The swelling was explored on March 12th and was found to be a small cyst surrounded by chronically inflamed tissue. The cyst was removed and the wound was stitched up, a drainage-tube being left in position for 24 hours. The wound healed by first intention. The pathological report which reached me subsequently says:—"Description: Thick-walled cyst of the breast. Histological examination. Chronic mastitis."

The patient came under my care again late in the year 1906. The note states that she is a well-built and well-nourished woman with a scar one inch above and within the right nipple. There are two tense and circumscribed swellings in the upper part and outer quadrant of the right breast. The swellings measure about half an inch in diameter. They are freely moveable under the skin and in the breast tissue. There are four or five similar but smaller swellings in the lower and inner quadrant, and three swellings of a similar nature in the upper and inner quadrant, so that the right breast contains at least nine separate cystic swellings, whilst in the left breast there is one similar cyst measuring about a quarter of an inch in diameter and situated in the upper and inner quadrant. The patient said that her right breast was always painful, and the anxiety which it caused her prevented her from following her occupation of teaching. At her earnest desire, therefore, I excised her right breast on Dec. 27th, 1906. An incision was carried round the lower half of the circumference of the right mamma. The skin and

subcutaneous tissues were dissected off the whole of the mammary gland, which was then removed, leaving the nipple and the skin untouched. The cyst in the left breast was afterwards removed. The wounds healed by first intention. The pathological report upon the right breast states, "Chronic interstitial mastitis with cysts and much overgrowth of the acini. There is no intracystic growth."

The patient wrote to me in December, 1907, nearly a year after this operation: "Since July I have been much better than before, and I certainly feel that there is no further development either in the breast itself or under the arm. I have had much less pain, at least it is not so continuous as it was before, and I believe that the lumps are decidedly smaller." A few months later, in April, 1908, she wrote: "I have been troubled again about my breast as I have had a good deal of pain. The lumps under the arm are no worse, nor, so far as I can tell, is there any noticeable change in the breast itself, except in the matter of pain. About five weeks ago it was very bad, but for the last ten days it has been better." When I saw her a few days after this letter I found that she had lately had influenza and was depressed by the attack, so that she had felt the pain more acutely than usual. Examination showed that her left breast was free from nodules and was soft, but that there were two enlarged glands in the axilla. I reassured her, ordered her a belladonna plaster, and gave her a prescription for a mixture containing iron and nux vomica.

She wrote again on Jan. 30th, 1910: "I cannot answer your questions quite so satisfactorily as I could wish, and yet I feel that I am no worse than when I last saw you—in fact, I think that I am better. To all outward appearance the breast is quite normal. I am never entirely free from pain for many days together, but it is as much in the shoulder and under the shoulder-blade as anywhere. I have occasionally what I may describe as a neuralgic pain in my arm and then I resort to aspirin. The glands under the arm give no pain or discomfort now, and unless I actually seek for them I forget their existence. They are still present, but I fancy that they are smaller. The little soft lump which has always been near the nipple is also there. I think it varies in size from time to time, but if it grows at all its growth is very slow and it seems a little harder."

This is an interesting case because it belongs to a difficult group of breast tumours, and I have been able to follow the course of the mastitis for six years, from a time when the breast was healthy until the inflammation has become chronic. The inflammation began slowly, without pain, and from no known cause. One breast became affected and a single cyst was formed. This was followed by a period of acute inflammation with the formation of many cysts attended with so much pain that the breast was removed by a plastic operation. Both breasts were affected at this time and the axillary glands became enlarged. This period of activity was followed by the present state of quiescence. I do not know whether this is a common history in cases of chronic cystic mastitis, nor do I know the relationship which this form of inflammation bears to carcinoma at some later period.

(C) CONGENITAL CYSTS.

Lymphangioma.—The last group of cystic tumours of the breast to which I wish to call attention are the congenital cysts, for of the hydatids I have no experience. The congenital cysts occur in very young children, and they are usually of the nature of lymphangioma. The following case is an excellent instance:—

CASE 15.—A boy, aged 3 years, was admitted into the Victoria Hospital for Children under my care with a swelling of the left breast. His mother said that his breast had been increasing in size for the last 18 months until it had grown to the size of half a Tangerine orange, but it had never been painful. I removed the breast, which is preserved in the Museum of St. Bartholomew's Hospital (No. 3142*d*), where the catalogue states that, "It shows a cystic growth in the tissues beneath the breast, probably originating in dilated lymph spaces. Besides the large multilocular cyst which is visible, a number of small cysts are scattered through the fat. The nipple and the breast itself are normal." The tumour, therefore, is a cystic lymphangioma of the same type as that which is not uncommonly seen in the necks of children, though it is rare on the trunk.

These cases are examples of some of the forms in which cystic disease of the breast presents itself to our notice. The fact that all but one have come under my own observation shows that they are by no means rare, whilst the mistake that I made in the recognition of one of them shows, perhaps, that they are not always easy to diagnose. The lessons to be learnt seem to be, in the first place, that our minds must not be filled with the idea of scirrhus to the exclusion of every other form of tumour when we examine a breast which contains a tense swelling in a woman of middle age, even though there be some enlargement of the axillary glands. A careful examination should be made in such cases to ascertain whether the swelling is more tense, more elastic, and more circumscribed than is usual in carcinoma. A patient with a tumour of the breast is generally examined whilst she is sitting in a chair, because she walks into the consulting room. It is better, I think, to examine her when she is lying upon the couch in every case where there is any doubt. The recumbent position allows the breast to lie upon the chest wall instead of hanging away from it, whilst the pectoral muscles are relaxed, and the exact conditions existing within the mammary gland can thus be determined more accurately. There is no great difficulty in making a correct diagnosis when fluid can be squeezed out of the nipple, nor when there is a weeping discharge from it; nor can a cyst be easily overlooked when it is thin-walled and superficial, nor when there is evidence of chronic mastitis in one or both breasts. The really difficult cases are those where the cyst is single, not very large, thick-walled, and surrounded by glandular tissue in a state of chronic inflammation. Instrumental exploration alone will reveal the cyst with certainty in these cases, and I prefer incision to aspiration or puncture with a needle, because the cyst wall may lie so deeply or may be so tough that it is not readily punctured; or the contents of the cyst may be too thick to pass along the needle or cannula; or worse still, there may be an intracystic growth or a nodule of commencing cancer in its immediate neighbourhood. Due attention, also, must be paid to the history given by the patient. We are a little too apt to think that cancer occurs more often than is really the case in breasts which have been damaged by long antecedent inflammation. In a certain proportion of cases it is so, but such an inflammation may also be followed by chronic mastitis and the formation of a thick-walled cyst about the time the breast undergoes the physiological changes of the menopause. In some cases, too, it happens that a cystic tumour may disappear, or at any rate become smaller for a time, and if there is such a history it may be accepted as confirmatory evidence, although patients with undoubted carcinoma sometimes bring themselves to believe that the tumour varies in size.

The outcome of what I have said is to show that cystic disease of the breast is not a distinct entity. It is associated with almost every variety of disease of the mammary gland, and requires careful investigation which is best carried out by a combination of clinical and pathological research.

HEART STRAIN AND DILATATION.[1]

BY J. F. GOODHART, M.D. ABERD., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL, ETC.

IN opening this discussion to-night will you allow me first to say, in explanation of what follows, that I am not here at my own instance, but by the kindly pressure exercised by the President upon an old and unwilling friend.

The subject is a very intricate one if fully considered; I hardly appreciated how much so till, after I had put my notes together, I began to criticise myself from out of the mouth of some most illuminating literature from certain of the giants of our day. I will confess that I went as far as anathematising your President's powers of persuasion, and I tremble still as I venture to put thus thinly before you an entirely clinical aspect of the case as it has come before me. But I do not think it will be waste of time to put the matter thus, for the subject is a very discussable one, and the paper will serve as the peg upon which to hang the remarks of subsequent speakers, which will be much more valuable than anything I have to say.

I shall consider both strain and dilatation more or less together. I feel compelled to do so, because strain, although it may be very real, is to my mind an intangible sort of thing and needs to be stiffened by some definite change of structure, although the two may not necessarily occur together. Now strained hearts, so called, are constantly in evidence; I surely do not exaggerate in speaking thus. With what body do they thus come before the physician? They have usually been where some muscular exertion has been undertaken, by male or female mostly young, and often apparently of a very insignificant character. The symptoms appear to be unnatural sensations of illness: perhaps nausea; perhaps fainting; the breath sighing; irregular action of the heart; collapse; sensation of impending death, perhaps, in some few cases. Then there come pains of various degrees and kinds over the region of the heart, and other sensations of general decrepitude such as extreme lassitude on the smallest exertion. The heart is then examined, and the impulse is found a little outside the normal;

[1] A paper read before the Medical Society of London on Nov. 28th, 1910.

the beat wants in decision and varies in force; not infrefrequently, I should say, it intermits. There may be no murmurs of any kind, or if there be, there is a systolic bruit at the base, usually over the pulmonary valves, and, or, a systolic murmur towards the apex which alters considerably in area and intensity as the subject changes from the erect to the recumbent posture, when it is likely to spread all over the region of a line drawn from the impulse to the pulmonary valves. Rest of a prolonged and more or less rigid kind is generally ordered. Here is my text:—

A boy, aged 18 years, at one of our public schools two and a half years before I saw him had taken part in a steeplechase and sports, and came home with "a big heart, a systolic murmur, and a questionable friction sound." He was kept in bed and got well. He was kept quiet afterwards, but he still had pain in his heart region if he ran much, and also under such circumstances would feel faint. His nerves were upset; he would have been in the eleven, but he got too nervous. He was a fine healthy fellow with phosphatic urine and a trace of albumin, but otherwise without discoverable fault. Eighteen months later he came to know if he might row at college. His medical adviser there had said he might, but Dr. C. D. Bowdich Hale, his doctor at home, who knew him better, had said some time before that he might not. He was still a most splendid fellow in physique, and I really could not say he must not, but I said take it easy. Well, he did row, and went to pieces, and a localised systolic murmur again developed. A consultation was held, and he was ordered to do nothing for a long time, my note says for three years, and I understood that this was because of the condition of his heart. Some four years later I saw this young man again. He had been overworked at a mission and had suffered from dyspnœa, and pain in the cardiac region, and faintness. Llangammarch being near his home he was given there a modified Nauheim course. When I examined him afterwards his heart appeared to me to be still perfectly sound. There is one other point in the case that seems of importance—viz., that some few years before I had seen this patient's father suddenly taken with ptomaine poisoning, and what was supposed to be a most alarming cardiac failure. He had been tremendously overworked, and was seized suddenly with a bad faint, but by the time I arrived there could be no doubt that the then condition was essentially nerve and not heart.

Another case is that of a healthy man, aged 35 years, certainly coming of gouty, and probably of nervous, stock, who some years ago suffered from nervous dyspepsia. He was a man of intellectual pursuits, working anxiously, and giving little heed to his physical development. He took a holiday and commenced it with a bicycle ride of excessive length, and not long after, impelled, I suppose, by the invigorating air of the Swiss mountains, he overwalked himself. After a few days, without apparently feeling much amiss, he suddenly fainted, and after a few days he had another faint, and he subsequently came under notice, with some pain about one shoulder, a systolic murmur at the base of the heart, and a feeling of the necessity of deep inspiration which came on especially at night, and which made him feel, he said, that if he did go to sleep he would never wake up again. But what was the more noticeable to his friends was an excessive decrepitude in walking, and the impression that he gave of being so very weak and really ill, and this two to three months after the original strain. There was no increase of dulness, a little only of varying force in the several beats of the heart, an occasional systolic murmur—nothing pointing to disease with any certainty.

Of dilatation of the heart it may perhaps be said that there are two sorts of cases met with, or indeed three, like the three Johns of the "Autocrat of the Breakfast Table." But of one of them (the real John) I do not propose to speak otherwise than incidentally. Of the first class there are two briefly stated. Both are women; both are very stout; both are nervous. The one of about middle age lost her husband a year ago, and has "felt mouldy" ever since, and, not unnaturally, wants to be better. She has been told that she has a dilated heart, but that there is no organic disease. The strain of the natural processes of life appears to have proved too much for it. Her symptoms of this are entirely general. She is not well, "so tired." She is so stout, that it is impossible to obtain any reliable information as regards her heart by percussion, but the sounds are perfectly natural; they are not unduly conducted into the axilla; the action is quite regular, and the pulse tension is under, rather than over standard, 110–120 R.R.

The second case is a woman, aged 39 years, who has had much out-of-health-ness in her life. Her nerves went to pieces after influenza, and again after a course of thyroid extract for the relief of her extreme obesity. Some years ago she went to Nauheim for baths, but they were too much for her, and she only had a few. She came for degeneration of her heart and vessels and to know if it were worth her while to undergo another Nauheim course. That she is an unsafe life is clear, and an unhappy one also, for she is always in misery, but so far as her heart was concerned to my ear it was perfectly sound. There was no murmur; no palpable impulse; the heart's action was quite regular; and the pulse tension only 120–130.

Of the other class I must add a little more, for although much the same forerunning conditions may be at work, added thereto are illnesses of many trivial sorts, more especially ephemeral fevers in young people, but all sorts of temporary disturbances, leading to feelings of general malaise, which in sensitive people lead them to consult a medical man. When so doing the heart's rhythm is found to be disturbed in some way or another, the impulse of the heart is found to be outside its ideal limit; quite possibly a murmur is heard, such as has been already shortly described, and according to some there is an increase of the præcordial dulness. For all these cases rest, and generally prolonged rest, is ordered, combined with one form or other of treatment directed to remedying the dilatation, and in my experience by far the most important sign of improvement or recovery is judged to be the movement inwards of the visible or palpable impulse of the heart, which is anxiously looked for day by day as it provokingly varies, now in, now out.

It is, I think, almost entirely upon this position of the impulse and upon the præcordial dulness that the diagnosis of heart strain and dilatation is so commonly made, but they are surely quite insufficient of themselves. Increase of dulness, fairly reliable as it is for enlargements of the right side of the heart, is of very little value when dealing with the apical section of the organ, and I hold that, except perhaps by radiography, it is impossible to obtain much reliable evidence of the lower and outer limits of the heart when it comes to attempting to estimate variations of relatively small size taking place within short intervals of time. I do not believe radiography can do it, when you come to consider the moving heart and the rapidly changing conditions of the environment—the lungs, the thoracic walls, and the diaphragm.

As regards the impulse in relation to the chest wall. No doubt in general terms it is a fairly constant anatomical landmark, all things considered. But what of the several conditions that tend to alter it when we come to try to precisely fix its limit and to judge of its value as an indication of dilatation? Suspended as is the heart between the lungs, and resting upon the diaphragm, it must vary in position constantly, with the varying *substance*, *distension*, and *position* of these surroundings. Again, we are dealing with a *muscle* and therefore the position of the impulse upon the surface will vary with the tone and precision of the muscular contraction. The ventricular muscle in systole twists up into a tight spiral. But does this constitute the complete history of any living muscle? Examine your own heart after dinner, and in bed at night when lying on your left side, and I shall be surprised if it does not tell to many quite a different tale. I cannot imagine any living fibre acting hour in and hour out, through days and weeks and years, with any rigid mechanical machine-like precision such as this. Could it last if it did? A very considerable latitude must be allowed to contraction, and contraction in the healthy physiological play of any muscle. The general result is accomplished truly, but not always with a vigour of equal value; and unless this vitality —this individuality of muscle fibre—so to speak, be allowed for, I cannot imagine how all the varieties of sound and murmur that we hear are to be explained. How is one to explain, for instance, some of those very common murmurs at the apex that are produced in a moment on suddenly shifting the position of the body? Muscular distension or

relaxation has a mean but healthy excursion on either side, must by no means be neglected, and in a series of cavities linked together thus the shape of the organ will vary somewhat in accord, and beat by beat. This is another reason why percussion can be no adequate or reliable gauge of what I will venture to call the *physiological play* of the healthy heart. Of the existence of such play there can surely be no doubt. To what extent this variation reaches I do not think that at present we have any accurate knowledge. It is easy to see that information is very hard to obtain; but my own observations lead me to say that the considerable alterations in size that have been supposed to be indicated by percussion and to become reduced at once by bath or exercise can have no real existence and no bearing upon any dilatation that I understand. Then the shape of the chest is over and over again ignored when judging of the value of the position of the impulse, and a heart is said to be enlarged and dilated because from this cause also its beat is more diffused and external than it should be. But what else is to be expected in the narrow, miserably-shaped chests that one is meeting with so often? The heart is almost certain, in such circumstances, to occupy more of the front of the thoracic cavity than it otherwise would.

When one comes to speak of murmurs as evidence of dilatation, I am then perhaps upon a more debatable ground, for there are many cases in which anyone must own to considerable doubt as to their cause. Starting from the fact, long well recognised, that there are many cardiac murmurs that are not valvular and are of little importance, I myself would go further, and say that many murmurs that seem to be regarded as evidence of valvular or, perhaps still worse, of muscular disease are, from the absence of symptoms of ill health, of some other source of production not to be explained with certainty, except that they are *functional*, if we may use that term to exclude organic changes in the valves or muscle. I say this in face of the admitted fact that many of such murmurs, though variable, are of great persistency. It is usually supposed that functional murmurs indicate some deterioration of blood or tissue, the which, as soon as it is removed or repaired by tonic or rest, will disappear. This has not been my usual experience, however. I should say some follow the rule, but many will continue for long, sometimes for many years. Yet there will be no indications of heart failure. These things are common in boys at school and in young men who will take as much exertion as others and who have no distress or knowledge of any incompetence in their daily undertakings. I have known a large number of such conditions first discovered in an examination for life insurance, and which have led to refusal or postponement in consequence. Many are in nervous subjects, who suffer from "the heart in the mouth" of the embryo orator or cricketer or performer in public of any kind, and I have little doubt that a large number of these murmurs are the result of the physiological play that I have alluded to. Long years ago we were shown and taught—oh! physiologist, think leniently of me when in my mellow years I call up the shade of Wilkinson King—that on the right side of the heart there is a safety valve apparatus that allows of regurgitation, and by so allowing it fulfils a necessary function. Surely, also, under appropriate conditions regurgitation is to be expected, and looked for upon the left side of the heart, for it seems to me unreasonable to suppose, as I have already said, a nervous muscular organ with a throbbing vitality such as the heart possesses to be always in tone. And to this purely physiological up and down—I will not call it either failure or imperfection—may be attributed many of the muscular rumble murmurs, many of the systolic souffles, many of the purely postural murmurs. Many of these last must, I think, be true mitral leaks, although not due to disease. One is entitled quite consistently thus to speak of *valvular* leakage without disease.

I willingly admit, however, that as regards their origin in many cases of this sort it is quite permissible to remain in doubt, all I maintain being that it is very necessary to keep the various alternatives in mind and that one must not conclude in favour of dilatation without very careful consideration. I have often wished in regard to these conditions that it may be so much a matter of nervous impulse—and it would not be difficult to arrange, I should think—that some ingenious mind would devise a simple stethoscopic apparatus, electric or other, by which to examine the heart at a distance while the patient sleeps. Methinks that many a sound or action that now causes doubt might be more certainly relegated to the region of the unimportant.

One more argument may still be adduced against the too prodigal use of the term dilatation, which is often neglected: it is that the symptoms for which men and women apply for treatment are not such as are found in cases where dilatation is beyond dispute. Fainting is perhaps one of the commonest of all symptoms in these cases of spurious dilatation. It is a prevalent belief amongst men and women that fainting means jeopardy because of "weakness" of the heart. There is no doubt that the same idea is pretty deeply cut into the medical mind also. Why not? It seems so reasonable. Yet there is no idea more absolutely contradicted by experience. Do people with well-marked disease of the heart associated with dilatation faint? Surely they of all cases ought to, if fainting be a sign of heart disease. What does your experience teach you? I will hazard a guess that it tells you this: that fainting, as a symptom of pronounced heart disease, is so rare that probably few here to-night have ever seen it happen. And there is good reason why. The vascular mechanism prevents it, and a dropped beat in the pump is taken no instant account of in the capillaries, or in the nutrition of the brain upon which function depends. Faints are peripheral phenomena, and due to peripheral spasm, or relaxation, to nerve storm, and so on, and with them the pump has little to do. Thus, by the way, it is that an intermission of the heart beat, if unassociated with any obvious disease, is one of the most unimportant of cardiac aberrations, and a weak pulse, made so much of too often, has but seldom any sinister meaning *quâ* heart.

Another very common complaint of these people is that they are dreadfully tired; the least fatigue is too much for them. Is this a symptom of pronounced disease of the heart? By no means. Systemic fatigue, as Clifford Allbutt happily calls it, is no indication of heart failure.

And what of all the other signs—the pain in that region, for instance, is that a definite sign of a damaged muscle? What sufficient evidence is there that the heart shows more than a dull muscular sense? Is there not plenty to indicate that that surface area is a neuralgic one like the sciatic region—the shoulder, the face? What of the sighing respiration, the collapse, the experience of dreadful illness, and so on? Is it unwarrantable to say, as an encouragement to one who thus suffers—I don't dispute the suffering, only the cardiac origin and the danger to life—"If you are able to appreciate your sensations so acutely you may be pretty sure your nervous centres and your heart are still much too vigorous to be anywhere near the point of death." Heart disease (within the confines of which I emphatically include dilatation of its muscular wall) produces the very opposite of this; it leads to congestive stagnations, and therefore to somnolence and mental hebetude; to that Crossing of the Bar, of which but the one in a thousand, perhaps not that, thank God, is able to recognise the signals when actually passing over it.

Now what do I suppose to be the condition of strained or dilated hearts at their onset, under such exertion as may have happened? As I try to picture them I see first of all a presumably healthy heart, strung for a life of, say, 60 years of wear and tear. Is dilatation so easy a thing to bring about under such conditions of temporary stress as have been laid upon it? Can it be admitted that it is so frequently the cause as to explain the many cases that one sees? Take the young man after a well-contested race, and what is the actual condition of his heart? He looks bad enough, certainly, and temporarily there is, no doubt, often a considerable over-distension of the right side of his heart—a condition I should suppose for which Dr. Gee years ago suggested the term asystolism. But I take it there is little evidence of mischief on the left side, and the man is simply played out from excitement and physical expenditure; his nerve current has for the moment ceased to run; and the heart is therefore, as all the other viscera, running on its own, the engine being for the moment shut off. If it were possible to force it, then and there, to fight its battle o'er again, death or irreparable damage would be sure to follow. But is the muscle there and then *ever stretched*, that is dilated? This is, of course, possible for a few cases, but for the many that *powerlessness in living*, that cardiac atony that

looks so ill, is the sign of the heart's health, and in a few minutes, a few hours, a few days, it will be working as well as ever. In some few there will remain those signs and symptoms of doubtful meaning of which I have already spoken.

The question in my mind is whether even true heart-strains, by whatsoever evidence it is possible to locate them, are not due to defective innervation—abortive messages—rather than to failure of response on account of damaged (over-stretched) muscle. But in saying this one would not wish to dispute, for one cannot doubt, that a place must be reserved in cardiac pathology for the sometimes result of actual and progressive morbid changes starting from early conditions such as these, and Dr. R. W. Michell's observations at Cambridge on the initial and later stages of what appears to have been genuine cases of the strained heart are very suggestive. But it interested me much to read that as regards *dilatation* that persists he had never found it, except in such who had in addition to strenuous exercise suffered from diphtheria or rheumatic fever. I take it that in general medicine we have a good illustration of what chronic strain *will* do in some of the many cases that one meets with of the dilated heart of chronic renal disease. But spread over so long a time, this is probably an adequate cause; certain strenuous muscular occupations will, no doubt, do the like, but I doubt if such chronic processes give any justification to the term "dilatation without disease," which I confess to cordially disliking, because it is just here that over-anxiety is likely to step in and do harm, and where the true measure of the physiological capacity of the heart for labour needs to be correctly appraised. Errors must, of course, be made on either side. I do not doubt that any of us may underestimate the risks of exertion in a weakling's heart. Still, on the whole, one cannot but come to the conclusion that the heart muscle has a magnificent power of resisting strain, and that dilatation is seldom, indeed, other than a *result*, and *late stage* of real *disease*. Primary dilatation is surely very infrequent, except perhaps as senility advances and degeneration has taken place.

Whether after all this is said we can entirely do without some term such as acute or temporary dilatation for some few cases of sudden overstretching of the muscle wall I hardly feel inclined to decide. There are, of course, cases where, as the result of heavy work, *something* suddenly happens and the heart dilates, and perhaps this may be more often than I may seem to allow. To guard against that possibility I certainly hold it to be necessary that would-be athletes should be carefully selected, and boys graded and inured by gradual training, as is done now in most of our large schools; but in true dilatation I think one may fairly expect some special indications to suggest caution in the particular case. A sudden rupture of a valve is to the point. In such cases the symptoms are usually immediate and severe, and it does not take long to find out that something untoward has come to pass. In the cases of which I have been speaking, this is seldom or never the case, and therefore I have come to think that dilatation, as a condition easily caused, is more often in our thoughts than the frequency of its occurrence would seem to justify, and that by over-nursing it we prolong the state that we set out to cure.

But I have yet to give a still wider application to these remarks by including within their scope a large group that belongs to the decadent period of life. I may, perhaps, designate it as "the irregular heart of the over-fifties." The heart in such a case seems to tumble about in a most erratic fashion—if so I may speak when Dr. James Mackenzie has in this region rendered such distinguished service by his attempts after reduction of chaos to order; yet there may be no murmur and no signs of cardiac failure. These people will do a good day's work, yet they sometimes faint; they are sometimes giddy; the heart at times will quite suddenly change its rhythm and become quite regular, and then again relapse. One may see a like phenomenon in certain cases of tachycardia, the rapid action ceasing suddenly and being replaced by a slow movement. Often have I wondered, as you must have done, how the circulation could be carried on in such circumstances. There can be no doubt about the absence of all signs of cardiac failure. Indeed, when these occur my case fails, and dilatation has probably occurred. It is, I should think, not unfair to argue that the muscle cannot be of so very inferior a quality if it is able thus to perform its duties when acting at such a disadvantage in this higgledy-piggledy fashion. And thus questioning, I fancy that there may be a still deeper root to the matter than an essential muscle fault; that some of these cases are early signs of a *nervous centre growing old*; and that the faintness, giddiness, and irregularity of the heart may be, not cause and effect one way or the other, but special sense centres and heart both giddy together as the result of some deep-seated central nerve storm or degeneration. Many a time have I seen this condition come on in men and women who have lived a hard life of mental stress; several times, too, have I known it associated with the vertigo and loss of consciousness that has sometimes been called senile epilepsy; I have seen it come and go with an attack of gout; and I incline to link it with some cases of Stokes-Adams disease, which in like manner I have seen come and go in obedience to a similar toxic state and to the dictates of an epileptic storm. Some of these cases are no doubt cases of degenerate muscle, but I have doubts about many of them, and it has seemed to me that they do better if allowed to take moderate exercise and to live in conformity with the time of life to which they have attained than if, as cases of fatty muscle, they were condemned to bath-chair and bed.

To sum up, then. True heart strain—by which I understand a state of muscle that, if not dealt with by retreat from all active exercise for long periods, leads to dilatation of the heart—is a rare condition. Personally I cannot remember to have ever seen it, but then I should not do so. Dr. Collier, Dr. Michell, and those who have to supervise athletic exercise in its home are the men to determine both its frequency and its signs and whose opinion one would be glad to hear to-night. Dilatation of the heart, in its beginning, is evidently not easy to determine with certainty, for it may share signs and symptoms in common with many emotional and other nerve disturbances of which the heart is a past-master of expression. Cases of doubt one must admit to be common, and they call for circumspection as regards their management, but one must beware of timidity, and I cannot but think that this has of late years been much abroad to account for the frequency and the looseness with which the term dilatation of the heart seems to have been applied.

Portland-place, W.

FURTHER REMARKS REGARDING THE MOTOR FUNCTIONS OF THE STOMACH.

By H. M. W. GRAY, M.B., C.M. ABERD., F.R.C.S.EDIN.

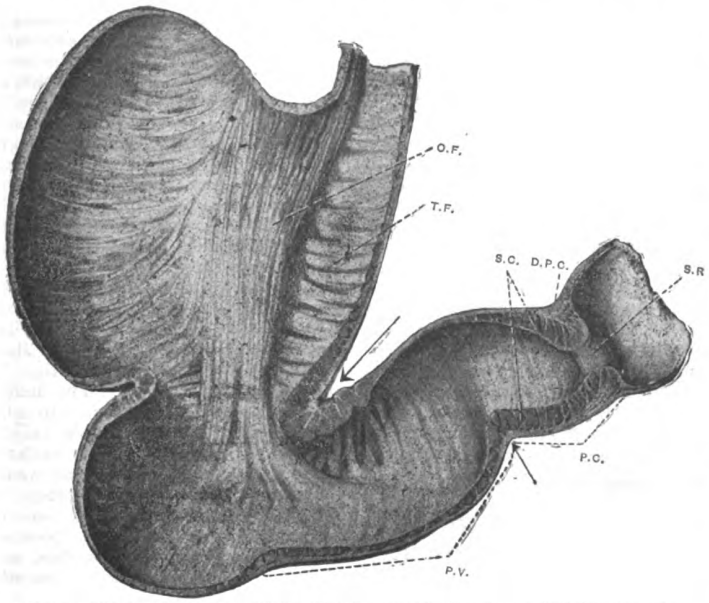
SURGEON AND LECTURER ON CLINICAL SURGERY, ROYAL INFIRMARY, ABERDEEN; SURGEON TO THE ROYAL HOSPITAL FOR SICK CHILDREN, ABERDEEN.

IN 1908 I published papers[1] in which I urged the importance of the "middle sphincter" of the stomach. Since then there have been many statements made, due chiefly to the interpretations of radiographers, which require criticism, because there is a danger of these statements being accepted as facts, whereas they seem, in absence of proper confirmation, to be more fanciful than truthful. These observers are seemingly unwilling to accept the presence of a "middle sphincter" of the stomach merely because it cannot be always demonstrated post mortem. Many observations, however, show that such a physiological "middle sphincter" does exist, and that in normal stomachs the parts of the organ on each side of this "sphincter" must be regarded as acting separately. The "middle sphincter" can be likened in some manner to the pylorus in that it holds back the stomach contents in the cardiac portion until they are in proper condition for being passed into the pyloric tubular portion, just as the pyloric sphincter acts in retaining the pyloric contents till they are in proper physical and chemical condition to be treated in the duodenum.

Several recent radiographers and others assert that the pylorus during gastric digestion descends naturally below and to the left of the umbilicus. I beg of them to ask their surgical friends to note in how many cases, when the abdomen is opened, the pylorus can be pulled by the hand

[1] THE LANCET, Feb. 22nd (p. 549) and July 25th (p. 224), 1908.

of the surgeon *from* the situation in which we are accustomed to look for it *into* the position which these radiographers make it assume. One must regard the muscular coats of the stomach as being less vigorous than the prehensile muscles of the average surgeon. Here in the North, at all events, there are not more than 20 per cent. of the stomachs thus examined which possess a pylorus capable of being pulled even down to the umbilicus, and one must remember that many of these stomachs are likely to have an *abnormally* mobile pylorus. When one thinks of the matter it is difficult to explain why the more or less longitudinal fibres of the gastric wall, even although assisted by the weight of the food in the stomach, should pull the pylorus into a position below and to the left of the umbilicus. The circular fibres cannot do it. It must be remembered that even *if* the pylorus is not so limited in movement as has hitherto been described, yet no one has challenged the fact that the cardiac orifice is the most fixed part of the stomach. The longitudinal muscular fibres would naturally tend to draw a less fixed part in that direction. The observations of these radiographers, to my mind, confirm my own, and I still prefer my own interpretation. They say that carbohydrate food begins to pass through the pylorus (displaced as described) in 15 to 20 minutes, and proteid in 30 to 45 minutes. These are the times when I observe food beginning to pass through the "middle sphincter." I think that these gentlemen mistake the "middle sphincter" for the pylorus. My interpretation is strengthened by the observation that food is not seen to pass this point any sooner where the stoma of a gastro-enterostomy is properly placed in the pyloric part of the stomach, nor does the cardiac part of the stomach completely empty itself in a shorter time in such a case.



The anterior half of a formalin-hardened stomach after removal of the mucous membrane. The lettered references need not be explained. (Kindly lent by the late Professor D. J. Cunningham to illustrate previous articles.)

The clinical symptoms of an ulcer in the pyloric end of the stomach give further support to the probability of activity of this physiological "middle sphincter." In a large number of such cases there is a fairly well-defined interval of relief after the patient takes food. This is apt to give rise to the diagnosis of duodenal ulcer, but the two may be differentiated by the fact that the interval of relief is shorter in a case of pyloric ulcer and the site of both pain and tenderness, as well as the reflection of the pain, differ from those of duodenal ulcer. This interval of relief cannot be explained satisfactorily by neutralisation, by the food, of irritating acid which may be present. If this were so one ought to have a similar relief in the case of an ulcer of the cardiac end, but here the pain follows immediately the swallowing of food and must be due to mechanical irritation of the food. Radiographers observe that food, when swallowed, passes to the lower part of the stomach. If there were no "middle sphincter," and especially if the pylorus were displaced as they describe and therefore formed the lowest part of the stomach, then one would expect an ulcer in the pyloric end to give rise to immediate pain, but it does not, unless the stomach is dilated and the "sphincter" therefore obliterated.

Before leaving the question of the "middle sphincter" one may repeat that it is possible that the action of the "middle sphincter," plus the general good tone of the pyloric portion distal to it, is responsible for the prevention of regurgitant vomiting of bile, which occurs most frequently in stomachs which were atonic before operation, and which also occurs occasionally during the atonic period of convalescence after a gastro-enterostomy and disappears completely, often without any special treatment, as the patient generally, and the stomach particularly, gains strength and tone. In such cases, however, a habit may soon be formed, and it is well to stimulate "tone" by lavage and tonics which will act on the gastric muscle.

I think there is no doubt that food, when swallowed, goes directly to the lowest part of the stomach, which part, at the beginning of digestion at all events, is immediately proximal to the "middle sphincter." It is not apparently a question of ordinary filling up of a bag. Gravity has, to my mind, little to do with what goes on. I think that too little regard is given to the remnants of the alimentary tube along the lesser curvature of the cardiac portion, which were so clearly shown in some of the drawings of the late Professor D. J. Cunningham (see Figure). This tubular remnant is probably responsible for the carrying of the swallowed bolus to the most dependant part of the normal stomach, whether the person is in the upright or horizontal position. This occurs in spite of the fact that food is already present in the organ. Some radiographers have demonstrated "blobs" of food passing along this part—surely due to segmentation similar to that which takes place in the small intestine. Further, it is possible that the action of this tubular remnant may explain the phenomenon which occasionally occurs after gastro-enterostomy has been performed—namely, vomiting of pure bile mixed with food swallowed but a few minutes before. The bile, having regurgitated through the abnormal and improperly placed stoma, collects in the cardiac end of the stomach in such quantity that the taking of food (carried to the lowest part of the stomach) is sufficient to stimulate vomiting in an organ already irritated by the excess of bile present. The bile being nearest the cardiac orifice is ejected first while the food, being retained, may keep up the patient's nutrition. It has impressed one how such patients can complain of most persistent and voluminous vomiting and still be in such good condition. The explanation I offer is at least a feasible one. The action of this tubular remnant would further explain the immediate and uniform pain which occurs, whatever may be the position of the patient, in ulcer of the lesser curvature in the cardiac portion when food has been swallowed. One would expect, if gravity alone acted on the food, even although aided by the propulsive power of the œsophagus, that when the sufferer lay, for example, on the left side some amelioration of the pain after swallowing would be experienced, but this is not the case.

We shall, I think, as time goes on, hear less and less of closure of the stoma after gastro-enterostomy. In the few cases which I have had the opportunity of examining when the abdomen has been opened, even years after the operation, I have never found any indication of this having occurred. Modern careful technique in making the stoma, which practically ensures "first intention" of the wound at its margin, obviates any such closure. Examination of such cases with X rays after a "bismuth feed" has invariably shown that food continues to pass out through the stoma in certain, but possibly variable, proportion. The persistence of the stoma ensures a safety-valve action when necessary.

It has been very freely stated by surgeons throughout the world that if gastro-enterostomy is done in stomachs in which no pyloric stenosis exists the patients are frequently worse after the operation than before. This is said to be the case, especially, if no other demonstrable gastric lesion is present. The neurotic condition of the patients, instead of the inefficiency of the surgeon, has been blamed for the bad result. I have had such bad results, and I have taught according to the usually accepted ideas, but have never been quite satisfied that the statement is a correct one. In a case where gastro-enterostomy is done for duodenal ulcer where no organic pyloric stenosis exists the ulcer heals, the pyloric spasm disappears, and then results a patient with a gastro-enterostomy stoma present in a stomach which is otherwise normal, yet it is only the rare exception in such cases to have trouble. I believe that such so-called neurotic patients with prominent gastric symptoms are subjects of some lesion distal to the pylorus, whether it be in the gall-bladder, appendix, or other part of the alimentary system, and the gastro-enterostomy will undoubtedly make many of them worse than before because the "check action" of the pylorus will then be done away with, and food, probably undigested, allowed to go where it is not wanted. (If there is irritation in any part of the alimentary tract beyond the pylorus there is apparently a "message" sent to the pylorus to hold food back. In such cases digestion is therefore upset even to the extent of causing vomiting, when relief is obtained usually at once. If a gastro-enterostomy is done in such cases without removal of the cause of the symptoms, it is more than likely that the symptoms will be aggravated because this check action is rendered inert by food passing through the stoma.) I believe that as the principles exemplified in the valuable writings of the Mayos, Moynihan, and H. J. Paterson become more widely known and appreciated we shall hear correspondingly less of this "bogie." I think that the acceptance of the view I wish to combat has been rather pernicious in that it has led surgeons to take an unnecessary risk by excising gastric ulcers in cases where this is unduly difficult so as to avoid the performance of a gastro-enterostomy, which of itself will, I am convinced, cause healing of the ulcer. Gastro-enterostomy should be done as a routine in such cases in order to remove permanently the local conditions which have led to the formation of the ulcer and therefore to prevent further trouble. It matters not whether gastric ulcer is due to purely local causes or whether it is the result of a more general alteration in metabolism resulting in a vciious circle which brings about the breakdown in the stomach.

Aberdeen.

INTRA-MEDULLARY LESION (? GUMMA) OF THE SPINAL CORD WITH BROWN-SÉQUARD PHENOMENON AND RECOVERY.

BY ALFRED BERNSTEIN, M.B., B.S. LOND.,
RESIDENT OBSTETRIC ASSISTANT, LATE HOUSE PHYSICIAN, WESTMINSTER HOSPITAL.

A FEMALE, aged 18 years, was admitted to Westminster Hospital on Dec. 8th, 1909, under the care of Dr. F. de Havilland Hall, to whom I am indebted for permission to publish this case. The patient was admitted complaining of pain in the back of the head and neck with stiffness and weakness of the right arm and leg. She first noticed stiffness in the neck about three years ago. About two months ago (October, 1909) there was slight pain in the back of the neck radiating over the back of the scalp, especially on the right side. There was also some numbness on the posterior right scalp. This had continued till the present. In the second week in October there was some weakness in the right arm first noticed in the shoulder, which gradually got worse, and by Nov. 8th the weakness had extended down to the hand. About the same time there was weakness in the right leg, which also got steadily worse. There was no numbness, but some slight tingling in the finger-tips. The patient was a packer. She had an attack of influenza a year ago (December, 1908), and 10 months ago was greatly shocked by her father's death, and "had not been the same since." The father died from phthisis. The mother and the other children had excellent history—no syphilis, cancer, or tuberculosis.

The patient was a well-developed, intelligent, bright girl. Dec. 10th: Pupils dilated, equal, and react normally. External ocular movements normal. Fundi normal. Face, palate, tongue, muscles of mastication normal. No cutaneous anæsthesia to cotton wool. Diminution to pin-prick, heat, and cold on left side of trunk bounded by the middle line, and extending as high as the second left rib in front. Includes also left lower and upper limbs. There is a slight patch of anæsthesia on right lower scalp behind. Marked weakness right upper limb at all joints. No movement impossible except extension of interphalangeal joints. Weakness more marked in distal part of limb. Moderate atrophy of interossei, thenar, and hypothenar eminences of right hand. Diaphragm, intercostals, and abdominal muscles normal. Moderate weakness of right lower limb at all joints against resistance. No movements impossible. Wasting of right arm and leg, especially deltoid and hand muscles. Gait: slight dragging of right leg. Supinator jerks: R. > L. Knee-jerks: R. ++; L. = normal. Right patellar clonus and ankle clonus. Plantar reflexes and abdominal reflexes not elicited. Sphincters normal. No spinal rigidity or tenderness. Other systems normal.

Progress of case.—During the next week the physical signs became more marked, and by Dec. 17th there was ankle clonus on the left side but less than on the right. Likewise left knee-jerk became exaggerated, but not so much as on the right. The atrophy of the muscles increased, especially the hand muscles, which were extremely wasted, giving well-marked "claw-hand." About the last week in December there began to be an improvement, which steadily progressed. On Dec. 31st she had gained 2 pounds 10 ounces in weight. Right arm was slightly stronger and the fingers could be slightly extended. On Jan. 7th right arm and hand much stronger. Thenar and hypothenar eminences filling out and movements improving. No reaction of degeneration. Good reaction to faradism. K.C.C. > A.C.C. Jan. 14th: Sensation in left leg normal. There is now no ankle clonus on left, while that on right is much less sustained than before. Jan. 21st: Still steady improvement. Now only the slightest wasting and weakness of interossei. The other muscles almost normal. Walks quite well. At end of the month patient quite well, and when seen two months later showed no signs of disease and said she never felt better in her life. Lumbar puncture on Dec. 28th gave 25 c.c. of fluid under increased pressure. The fluid was normal, containing only one or two lymphocytes to 1-6 inch field, and cultures were sterile. Wassermann's reaction on Jan. 6th was negative. Unfortunately this was not done until antispecific treatment had been used some weeks, but there was never any reason to suspect either congenital or acquired syphilis, and there was little hope that the use of mercury would be followed by recovery. The treatment was inunctions of mercury together with massage, and internally potassium iodide. The mercury and iodides were well borne.

Remarks.—The lesion in this case was evidently situated in the right half of the substance of the cord, especially the anterior horn in the upper dorsal region. But the nature of the lesion is more difficult to determine. Tumours of the cord, tubercle, &c., a plaque of disseminated sclerosis, would hardly have cleared up so rapidly after advancing so far and so quickly. Neither would anterior poliomyelitis account for all the physical signs. Hysteria is excluded by the marked rapid wasting of the intrinsic muscles of the hand and the absence of other hysterical stigmata. The rapid development of all the symptoms followed by as rapid a recovery after anti-syphilitic treatment seem to point to the specific origin of the lesion, which is supported by the fact that mercury was so well borne.

Spinal gummata are very rare. Gowers and Williamson have described them in the posterior horn. They usually start in the membranes or roots, much more rarely in the substance of the cord, and there is as a rule some associated meningitis manifested by numbness and tingling in the limbs and perhaps some stiffness and pain in the neck. Unfortunately in this case lumbar puncture was not performed till more than two weeks after mercurial treatment was started. It was then quite normal fluid, though in excess and under pressure. Armstrong has reported a case of crural monoplegia with anæsthesia of opposite limb and Mott a similar case.

A CASE OF INTESTINAL OBSTRUCTION CAUSED BY AN ENTEROLITH SPONTANEOUSLY CURED BY EVACUATION THROUGH AN UMBILICAL FISTULA.

BY DAVID M. GREIG, M.B., C.M. EDIN., F.R.C.S. EDIN.,
SURGEON, DUNDEE ROYAL INFIRMARY; LECTURER ON CLINICAL SURGERY AND SURGICAL DISEASES OF CHILDREN, ST. ANDREWS UNIVERSITY; SURGEON, ROYAL VICTORIA HOSPITAL; HONORARY CONSULTING SURGEON, ARBROATH INFIRMARY.

THREE reasons justify the publication of the following isolated case—viz.: enteroliths are not common; they are specially rare in children; and enterolith obstruction is seldom recovered from by spontaneous evacuation through an abscess.

A scholar, aged 12 years, was admitted to my care in the Dundee Royal Infirmary on Dec. 23rd, 1909. He was the third of five children, one of whom had died aged 45 days from congenital icterus. His mother was well and the other children were said to be "fairly strong." His father had died three years previously from locomotor ataxia. The patient had never been a very robust child. Immediately after birth there seems to have been some inflammation about the stump of the cord and this culminated in an abscess which was incised, but it gave no trouble after that and healed well and completely after six weeks. He was solely breast-fed until he was nine months old, and though troubled with flatulence as a child, was fairly healthy during the first nine years of his life. During that time he was very difficult to please with regard to his food, and seemed to have a special objection to liquid in any quantity, and a predilection for dry food. There is no history of indulgence in porridge. At the age of 9 years he had two "convulsion fits" within a fortnight, apparently hysterical, on hearing of his father's death, and since then, his mother thought, there had been greater difficulty in pleasing him with his food. During the six months preceding his admission he had three attacks of colic or "cramp in the stomach," which came on from no obvious cause and lasted about 24 hours. Each attack began with pain in the region of the umbilicus, and was followed after a couple of hours' duration by vomiting. The bowels were not affected in any way, neither constipation nor diarrhœa being noted or complained of. The attack for which he was brought to hospital had come on ten days previously to admission. The usual pain occurred, was followed by vomiting, and was treated by hot applications. The expected relief in this instance, however, was not obtained by the usual remedies. The bowels were constipated, and the pain was not constant, though it varied much in severity. In many ways the attack simulated appendicitis.

On admission the child looked very ill; the tongue was dry and covered with thick brown fur and the lips with sordes. The temperature was normal, the pulse was 96, and the respirations were 20 per minute. The abdomen was scaphoid and symmetrical, and there was a pointing abscess at the umbilicus which was protruding, inflamed, and fluctuating. It was about this area that the pain seemed to culminate, and elsewhere the abdomen could be palpated pretty easily. There were no tumour, however, and no abnormal dulness. On the day following admission, though sick and vomiting, he was easier because the umbilical abscess had burst and was discharging offensive pus. Then for six days he had less pain and no sickness, and there continued a copious foul-smelling discharge which necessitated frequent dressing, but the boy did not seem to make progress. Two days later, after an increase of pain, the vomiting recommenced and he was unable to retain any food during 24 hours. He seemed thinner and weaker and there was still a large amount of pus pouring from the umbilical sinus. On Jan. 3rd, 1910, 11 days after admission, the sinus was cautiously enlarged under general anæsthesia and a drainage-tube was inserted. This was followed by a diminution of the discharge, but it was noticed on the 5th that there was some fæcal matter mixed with the pus. The slight improvement was maintained for a few days, but by the 10th he was again ill, and thereafter seemed from day to day to be losing flesh and strength. The sinus gradually drew together and appeared to be inadequate for the evacuation of the cavity it led to. Consequently, on Feb. 14th the sinus was enlarged by dressing forceps, and an attempt was made to provide more efficient drainage. This was successful to some extent. On March 5th, while the wound was being dressed, a rounded calculus-like mass presented in the sinus and was easily removed, its escape being accompanied and followed by an unusually large quantity of pus. From that moment the wound healed rapidly and the boy's condition materially improved, and he was discharged healed and looking well and stout ten days later. His general improvement was as striking and remarkable as the improvement in the local condition.

The structure which was discharged proved on examination to be an enterolith. It was globular, measured 2½ inches in circumference, rather larger than an ordinary marble, being smooth for the most part but not polished, and when dried its most striking feature was its lightness. It weighed 24 grains, and, indeed, was considerably lighter than a pith ball of equal size. It bears a striking resemblance in miniature to the concretions commonly found in the colon of the horse.

With the history this child presented, the imperfect health he had enjoyed, and the poor physique he had attained, even in the absence of a history of alternating constipation and diarrhœa, it is not to be wondered at that on admission the diagnosis of tuberculous peritonitis with perforation and the formation of a fæcal fistula was formed; indeed, it is probable that had it not been for the dangerous proximity of a fœtid sinus he would have been operated on under this supposition. Still less is it reprehensible that before admission the previous history, the sudden onset, the constipation, vomiting, and pain, should have led to the diagnosis of appendicitis.

The enterolith was of the light-coloured variety, and as above noted, there was no history of special indulgence in porridge, which is supposed to predispose to the formation of such avenoliths, or oat-stones. It is almost contrary to what one would expect, but characteristic of the condition, that the intestinal obstruction to which the "stone" gave rise should be of a chronic character and spread over years before the condition becomes acute. Where the enterolith lay in this case it is impossible to say. The sinus led from the umbilicus backwards into the right loin, but the obstruction must have been in the small intestine, for a foreign body of its size could not cause obstruction in the great.

There is a considerable, though scattered, literature on the subject, and its perusal and of that of intestinal obstruction from foreign bodies, suggests that in some cases of "gall-stone intestinal obstruction," where there is a history of years of recurring colic and vomiting but no jaundice, the "gall-stone" might prove to be an enterolith on investigation. In the above case the enterolith felt solid and heavy, almost stone-like, when first extruded and was quite as solid and firm as many a single gall-stone. It was only after drying that it assumed its pale yellow colour and showed its peculiar lightness.

Dundee.

NOTES UPON AN OUTBREAK OF ILLNESS DUE TO TINNED MEAT IN THE CITY OF CARLISLE.

BY JOSEPH BEARD, F.R.C.S. EDIN., L.R.C.P. LOND., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH, CITY OF CARLISLE.

ON August 26th last I received information of an outbreak of sudden and suspicious illness in the Denton Holme district of Carlisle, which upon investigation was found to have occurred in a number of persons who had partaken of the contents of a tin of American corned beef; 21 persons in all were affected, of whom several were said to be suffering somewhat severely. The illness appears to have manifested itself without any premonitory symptoms by the occurrence of vomiting, diarrhœa, pains in the stomach, and collapse, but fortunately the outbreak was not attended with any fatal result, and all those affected are now well.

I secured what remained of the suspected meat and divided it into two portions, one of which together with the tin I forwarded to the city analyst, Dr. R. Hellon, to examine

the specimen for irritant metallic poisons and any evidence of faulty tinning or accidental punctures in the tin; the remaining portion was forwarded in a sterile bottle to Professor S. Delépine of Manchester for the purpose of a complete bacteriological examination.

Having obtained a list of all who had purchased portions of the meat investigation was then made at each house, which resulted in information being obtained that ten families had made purchases of the meat in quantities of from two ounces to half a pound. In the 10 families 21 persons partook of the meat and in each instance the effect was practically the same, although in some cases the symptoms were more severe than in others. It will be observed that only a small quantity of meat in each case was purchased and the severity of the attack appeared to vary in direct proportion to the amount of the meat eaten, the worst case being that in which one person (a male adult) consumed a quarter of a pound. The earliest symptoms of the disease manifested themselves at periods varying from 15 minutes to 4½ hours after the consumption of the meat, but in the greater number of the cases the interval was about an hour, and in some of the cases in which the symptoms were said to have been severe medical men were called in. The meat was purchased by the shopkeeper from a firm of first-class American packers, and the particular brand of meat to which the tin in question belonged is a brand which has a good reputation for quality and packing.

It would perhaps be advisable here briefly to outline the information obtained with regard to the distribution of the individual portions of meat purchased.

A. purchased a quarter of a pound of the meat on the morning of August 25th, which was partaken of at breakfast by three persons, aged 24, 18, and 15 years respectively; all three were shortly afterwards seized with vomiting, diarrhœa, with collapse, and some loss of power in the lower limbs.

B. purchased a quarter of a pound of the meat in the early morning of the 25th, some of which she partook of and shortly afterwards exhibited the same symptoms as the previous cases.

C. purchased a quarter of a pound of the meat on the night of the 24th, which was taken by her husband to his work and which he ate at 3 A.M. on the morning of the 25th. He was shortly afterwards seized with violent pains in the abdomen, vomiting, diarrhœa, and collapse. He also lost the power of both legs and was removed from his work to the house of a relative who lived near, where he remained for about 24 hours in a dangerous condition.

D. purchased a quarter of a pound of the meat on the morning of the 25th, which was eaten at mid-day by her husband and two children. At 3 P.M. in the afternoon one of the children returned home from school, the husband had to leave his work, and at 5 P.M. the second child became ill; all exhibited symptoms of vomiting, diarrhœa, and collapse.

E. purchased a quarter of a pound of the meat on the morning of the 25th, which was partaken of by her husband and herself. The husband had to leave his work through vomiting and diarrhœa, and later in the afternoon she was attacked with vomiting, diarrhœa, and collapse.

F. purchased a quarter of a pound of the meat on the morning of the 25th, some of which she took for her midday meal, and within an hour she was seized with vomiting, diarrhœa, and collapse.

G. purchased one pennyworth (2 ounces) of the meat on the night of the 24th which she made into a sandwich for her husband. The husband ate this at 3 A.M. the following morning and was shortly afterwards seized with vomiting, diarrhœa, and collapse. The wife whilst making the sandwich ate a piece of about the size of a hazel nut and was seized with diarrhœa shortly afterwards but no other symptom.

H. purchased half a pound of the meat on the night of the 24th, which was eaten for breakfast next morning at 7 A.M. by her husband, two sons, and a niece. At 8 A.M. one son was seized with vomiting, diarrhœa, and collapse, shortly followed by the father, brother, and cousin exhibiting similar symptoms, with the exception of the younger brother, who had no vomiting.

J. purchased a quarter of a pound of the meat on the night of the 24th which she made into a sandwich for her husband, during which process she ate a small piece about the size of a walnut. At 1 A.M. the husband ate his sandwich, and at 3.30 A.M. he was seized with pains in the abdomen, vomiting, diarrhœa, and collapse. He managed to get home, and on arriving there found his wife in a similar condition. His wife was quite well in 24 hours but he was not fit for work for five or six days.

K. purchased a quarter of a pound of the meat on the night of the 24th, part of which she and her father-in-law partook. They were both seized shortly afterwards with vomiting, pain in the abdomen, and some collapse.

On August 29th I received the following provisional report from Dr. E. J. Sidebotham, assistant to Professor Delépine in the Public Health Laboratory, Manchester:—

> The specimen showed no appearance of decomposition, but it is extensively infected with micro-organisms. These can be seen with a low magnification forming colonies on the surface, and they have been obtained by cultivation from the interior of the meat. The forms so far isolated are not ones usually associated with cases of food poisoning. Further investigations are being made, and a report will be sent as soon as possible. The specimen is unfit for human consumption.

I also received the following provisional report dated Sept. 1st from Dr. Hellon upon the chemical examination of the meat:—

> In compliance with your request I have made a most careful chemical examination of the American corned beef which I received from you on 27th ultimo. My search has been directed chiefly to the discovery of the presence or absence of arsenic, tin, and lead, and incidentally to that of other metallic poisons. The result of my investigation has been to show conclusively the absence of any poisonous metal which could have caused the illness you have described to me. I am therefore convinced that if (as appears probable from the symptoms) this illness was caused by an irritant poison, the poison was not a metallic one.

On August 31st I received a further report from Dr. Sidebotham as follows:—

> The meat had no unpleasant smell and there were no signs of decomposition. On inspection with a low magnifying power numerous colonies could be seen on the surface. These were examined microscopically and found to consist of cocci and small bacilli. On cultivation numerous organisms were obtained both from the interior and the outer surface of the meat. These consisted of cocci of two sorts and a yeast. By anaerobic cultivation two sorts of bacilli were obtained. None of these organisms were of the sort usually associated with cases of the gastro-intestinal form of food poisoning.
>
> The following experiments were carried out. Three guinea-pigs and three mice were fed with portions of the meat; one of the guinea-pigs died in 48 hours, but post mortem there were no signs of gastro-intestinal irritation and no obvious cause of death was found. The other guinea-pigs and the mice were unaffected. Two guinea-pigs were inoculated subcutaneously with a watery extract of the meat and were unaffected.
>
> A substance was obtained by the chemical method used for isolating toxins. This was tested by subcutaneous inoculation of a guinea-pig and caused no ill-effects. The meat is extensively contaminated and quite unfit for food, but we have not succeeded in isolating the organism or substance which has rendered the meat pathogenic.

Whilst waiting for the report of the city analyst upon the condition of the tin, I wrote to Dr. Sidebotham asking him if he would supply me with further information relating to the morphological and other characteristics of the bacilli under observation seeing that they were, in his opinion, unclassified varieties, in reply to which I received the following report:—

> 1. A staphylococcus which produces yellow colonies on agar and gelatin, liquefies gelatin somewhat slowly.
> 2. A staphylococcus which produces white colonies on agar and gelatin, liquefies gelatin rapidly. These two organisms were very abundant, and in about equal numbers.
> 3. A small yeast which was present in very small numbers.
> 4. Bacilli of two varieties which were obtained by anaerobic cultivation of the meat, of which the relative numbers were not obtained. As none of these organisms showed any pathogenic action on guinea-pigs and mice it was not thought necessary to carry the investigations further.

Dr. Hellon's report upon the tin is as follows:—

> In compliance with your request I have returned to you the tin which contained the corned beef suspected of having caused the illness in Denton Holme, also the label which I detached from the tin. I have carefully examined the tin with a lens but have been unable to discover any perforation or opening through which air might have leaked in. As a test I filled the tin with boiling water, and after the water had cooled I carefully searched the outside of the tin with a lens for minute drops of water but found none. The loose top of the tin could not be subjected to this water test, but the lens showed no flow in the soldering through which air might have entered. I am therefore of opinion that the tin was sound and airtight.

The last two reports conclude the bacteriological and chemical investigation. The report of Dr. Hellon showed pretty conclusively that the meat could not have been infected after leaving the packers as a result of faulty tinning or subsequent accidental punctures; furthermore, it must be remembered that the principal organisms under observation were of the anaerobic variety. The questions for me to decide were: (1) at what period the meat became infected; and (2) whether the infected meat was responsible for the outbreak of illness.

With regard to the first question, the meat might have been infected at some period either before or during the process of tinning or after the meat was opened at the shop, but the latter theory is negatived by the fact that the principal organisms present were of the anaerobic group, that the portions of meat were purchased by the several householders so shortly after the tin was opened and eaten within a very short interval following—so short, indeed, that the amount of the growth of the organisms present in the meat would have been impossible, even assuming that they had been of the aerobic variety. Therefore, upon the evidence I am convinced that the meat was contaminated previous to, or at the time of, tinning at the factory in America.

In deciding the second question due regard must be given to the fact that not only was the history as to the consumption, onset, and other clinical features the same in each case, but also (*a*) that the vomiting, diarrhœa, and other symptoms came on suddenly and acutely within a very short interval of eating the meat; (*b*) that every person who partook of the meat was ill; and (*c*) that the meat in question was the only article of food eaten in common by the several persons affected.

Outbreaks of food poisoning are not altogether uncommon and do not always terminate so favourably as the one under review. In this class of poisoning the ill effects are due to the ingestion of pre-formed poisons which are elaborated by the micro-organisms in the infected food. The poisonous agent does not undergo any further bacteriological change in the human system, and thus, there being no period of incubation, the symptoms come on suddenly, which constitutes an important comparison to that class of cases in which the illness is due to the development or proliferation of the micro-organisms within the blood or tissues of the body.

In criticising the bacteriological reports, which were to the effect that neither the feeding nor the inoculation experiments upon the guinea-pigs and mice gave rise to a fatal issue, it must be remembered that the effect of all toxins is proportionate to the virulence of the toxin and the amount received into the system, and as there appears to be no doubt that the portion of the tinned meat eaten in each case was the cause of the illness, the experimental results by Dr. Sidebotham, together with the non-fatal result of the outbreak, confirms me in my opinion, as expressed to my committee in a report dated Sept. 2nd, that the toxins at the time the meat was eaten were in all probability not of a very virulent nature.

SECTION OF THERAPEUTICS AND PHARMACOLOGY.

Action of Sulphur as Intestinal Antiseptic.—Experimental Administration of Drugs of the Digitalis Group.

A MEETING of this section was held on Nov. 15th, Professor A. R. CUSHNY, the President, being in the chair.

Professor R. B. WILD (Manchester) read a paper on the Action of Sulphur and Certain of its Compounds as Intestinal Antiseptics. In addition to its action as a mild purgative, sulphur has a definite antiseptic action in the intestine owing to the formation of H_2S when bacterial decomposition takes place in its presence. To this action may probably be attributed the traditional efficacy of sulphur and of sulphurous waters in chronic gout and rheumatism, and in certain skin eruptions. The superiority of sulphates as purgatives is in part due to their reduction to sulphides in the bowel. The preponderance of plants containing sulphurous volatile oils among those used dietetically is remarkable. Long-continued administration of sulphur causes depression. Sulphur is tasteless, insoluble in the stomach, without action on digestive enzymes, forms in the intestine antiseptic substances which penetrate to all parts of the bowel, has valuable laxative properties, and is cheap.

Dr. H HUME TURNBULL gave a further account of the Experimental Administration of Drugs of the Digitalis Group under Dr. James Mackenzie and Professor Cushny, which the latter dealt with in his presidential address. Strophanthus was only about one half as active on man as digitalis, B.P. tinctures being used in both cases. Cases of rheumatic disease were most distinctly benefited, and especially those with auricular fibrillation. For the latter class of case the pushing of digitalis was the essential treatment. The drug was given in full doses until "physiological" effect (nausea, vomiting, headache, giddiness, &c.) appeared, then stopped and recommenced in smaller doses till the minimum amount which would control the heart was found. The intelligent patient could then be left to dose himself by his own sensations. In cases with partial heart-block great care was necessary.

A lively discussion followed, in which the following took part: Dr. HARRINGTON SAINSBURY, Dr. E. I. SPRIGGS, Dr. J. GRAY DUNCANSON, Professor WILD, Dr. H. H. DALE, Dr. CAMERON, and the PRESIDENT.

Dr. TURNBULL replied.

MEDICAL SOCIETY OF LONDON.

Heart Strain and Dilatation.

A MEETING of this society was held on Nov. 28th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. J. F. GOODHART read a paper on Heart Strain and Dilatation, which is published in full on p. 1607 of this issue of THE LANCET.

Sir R. DOUGLAS POWELL, in the course of the discussion that followed, said that he agreed with Dr. Goodhart that a large number of cases of dilated heart existed in the imagination of the observer. In regard to cases of so-called heart strain the most important point was that of diagnosis. It certainly was his experience that many of the cases in which the condition was brought about by excessive athletic exercises in which symptoms were attributed to the heart were cases in which there was a very great amount of anæmia. He had observed that people who had overtaxed their muscular system for a long time were apt to become anæmic. He had the utmost respect for the importance of X ray photography in certain conditions of the heart and aortic disease, but he did not think X ray photography was of much value in estimating the minute shades of differences in cardiac dilatation.

Sir LAUDER BRUNTON thought that there was much similarity both in pathology and treatment between strain of a joint and strain of the heart. If the strain of a joint was slight it was best treated by gentle movement from the first, but if it were severe perfect rest was required at first and gentle exercise afterwards, and the same was the case with cardiac strains. Cardiac dilatation might sometimes be due to causes in the central nervous system, but one of the most typical cases he had seen was in a healthy young officer who carried a heavy man on his back round the barrack yard for a wager. In disordered heart of advancing years one had to remember the importance of the general nutrition in which the heart shared, and exercise was often very beneficial for that.

Dr. HENRY DAVY urged the great importance of recognising the connexion of decayed teeth with the condition under discussion. He narrated the facts of a case of a patient of his of about 63 years of age, who was a teetotaler and never had syphilis nor any other disease, and yet had manifest atheroma of all his arteries and a hypertrophied heart with the apex beat well outside the nipple and a feeble unsatisfactory pulse, with an occasionally soft mitral systolic bruit after much exertion. He had always been athletic, had captained the cricket team at a public school, and was a university "blue" in cricket and football. He was said to have suffered from "heart strain" when at college and was just one of those cases which might be put down to over-athleticism. But that clearly was not altogether the explanation of his condition. A few months after seeing the patient his sister came under Dr. Davy's care in precisely the same condition as her brother; if anything, the atheroma and feebleness of the heart muscle were worse. That lady had never done any muscular exertion in her life; she had, on the contrary, always led a sedentary life, and the chief point in which she agreed with her brother was in having very bad teeth; in fact, neither her dentist nor Dr. Davy himself had ever seen teeth in a worse state of decay. It was clear, therefore, that the condition in the man was not due altogether to his former

athletic life, and Dr. Davy was still looking for a case in which muscular exercise had damaged a perfectly healthy heart.

Dr. W. COLLIER (Oxford) said he was often consulted in the case of athletes with definite dilatation of the right side of the heart, and occasionally mischief on the left, concerning the advisability of these patients indulging in hard athletic exercises, and in such cases he had vetoed such exercise. The physical signs and symptoms upon which he relied were abnormal epigastric pulsation and a definite murmur running up the left side of the sternum systolic in time.

The debate was adjourned until Monday, Dec. 5th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

President's Address on Some Recent Clinical Experiences.—Locomotor Ataxy.

A MEETING of this section was held on Nov. 11th, Sir JOHN MOORE, the President, being in the chair.

In his introductory address the PRESIDENT embodied notes of a number of cases, perhaps of every-day clinical experience, but which, in his opinion, threw more or less light upon obscure features in diagnosis and pathology or illustrated some practical points in treatment. Speaking of lobar distribution of pneumonia in childhood, he said that nothing was more remarkable in the epidemic history of Dublin during the last quarter of a century than the steady decline in prevalence of enteric fever, the all-but disappearance of typhus fever, and the ominous increase of acute pneumonia—a disease which was much more appropriately termed "pneumonic fever." This acute infection had, in fact, taken the place of the old classical continued fevers in the nosology of the Irish capital. Many of their pneumonia patients in recent years had been children of quite tender age. According to the old teaching one would have expected to meet with a lobular rather than a lobar distribution of mischief in the lungs in such circumstances. But the reverse was the fact. This point was illustrated by a series of eight cases of pneumonia in children aged from 6 months to 4 years. A further case of acute pneumonia was quoted to show that apical fibrinous pneumonia resolved slowly. And in yet another case lumbar puncture was performed with immediate benefit to the patient. Two examples of ataxic typhoid fever were described, recovery taking place in each instance. The President laid stress on the extreme therapeutic value of camphor as a stimulant, antiseptic and sedative. Two other cases were given in illustration of the diagnostic value of Widal's test. One, in which the test was negative, proved to be acute general tuberculosis. The address concluded with reports of a case of amyotrophic lateral sclerosis and of a remarkable staphylococcic infection causing a six months' fever and controlled by vaccination with an antistaphylococcic vaccine.

By permission of the President, Dr. W. BOXWELL showed another case of Amyotrophic Lateral Sclerosis. The case was an early one, giving a history of weakness and wasting in the hands and arms of only two months' standing. The patient was a woman, aged 20 years, who on admission to hospital showed the typical wasting and paresis of the hands and forearms. Her legs were also partially paralysed, with well-marked "dropping" of her right foot. There was no wasting of the legs, however, and the jerks were increased in all four limbs. There was slight increase of the "jaw-jerk," but no other evidence of bulbar involvement. When the patient came to hospital she could scarcely stand, and could not walk at all without assistance. She had, however, much improved, and could now walk pretty well, though the dropping of the right foot was still noticeable.—Dr. T. G. MOORHEAD said that this was the most marked and youngest case of the kind he had ever come across. He thought it was rather the exception than the rule to find an increase in the reflexes in the lower extremities.

Three cases of Locomotor Ataxy were exhibited as follows:—

Dr. J. F. O'CARROLL said the odd thing about his case was that up to two months ago the man was driving a car. While still driving he noticed himself staggering a little in his walk about August 1st. His sight had been failing since the beginning of September, and he could now see practically nothing. He had a primary atrophy of both optic discs. He had well-marked myosis, and there was no accommodation for distance other than the slightest in the right eye. He had anæsthesia and slow perception of sensory stimuli. Now and again there had been some slight incontinence of urine, which he was able to stop when he perceived it. He had had a good deal of constipation, and when he had a purgative his bowel prolapsed six or eight inches with little or no distress. He was also insensitive to retained urine, as 15 ounces had been taken away after he thought he had finished passing water. He was insensitive in the middle division of the fifth nerve to pain and touch. He had no history of lightning pains, but spoke of pains like rheumatism. He had no knowledge of having had syphilis, but he acknowledged that he had been in the way of contracting it.

Dr. J. B. COLEMAN showed a case of six or seven years' standing, the ataxy being badly marked. There was a history of lightning pains. There were Argyll Robertson pupils, loss of knee-jerks, and Romberg's sign. The patient had perforating ulcer of the foot. The ulcer began in a corn, which he cut. About six months ago a small sore appeared, which had gradually deepened. There was some suppuration but little or no pain. The ulcer was on the ball of the little toe.

Dr. M. DEMPSEY exhibited a case in a man 41 years of age. Twenty years ago he had contracted some venereal disease, followed by a slight rash on the skin. About four years ago he became dizzy and had to take to bed. As long as he was in bed he felt he had good power over his limbs, but he was unsteady when out of bed. Shortly afterwards his external rectus became paralysed. When he looked towards the right he saw two images. This was operated on and relieved to some extent. He had suffered from pains, which he described as boring in character, below the knee, not shooting but stationary. The pupil dilated when the neck was pinched. One was a little eccentric. His sensory phenomena were moderately marked. He had a little subjective anæsthesia. The fluid from a lumbar puncture taken that day showed a lymphocytosis. He had loss of heel-jerk and knee-jerk. His epigastric reflex was well marked; so was the umbilical.

NEWCASTLE-ON-TYNE CLINICAL SOCIETY. — A meeting of this society was held in the Geographical Institute on Nov. 10th, Dr. E. Napier Burnett, the President, being in the chair.—After an exhibition of cases to a large gathering, Dr. D. Wells Patterson read a paper on the Treatment of Certain Diseases of the Skin by Solid CO_2. At the outset he showed that the idea of treating certain skin diseases by means of cold applications such as ethyl chloride and liquid air was not a new one, but that in solid CO_2 we had an agent which was much more easily handled and therefore could be used in many different ways. He deplored the fact that as a rule extravagant claims were made for new remedies. He sketched the actual history of the use of solid CO_2. He then described the method of production of the snow, its moulding into pencils, and its application to patients. He noted that the aim of the treatment was to produce a certain reaction in the tissues, which reaction might be something between a slight erythema and a complete superficial necrosis of the skin. He urged the necessity of great care in its use because of the possibility of subsequent trouble arising, especially in tissues the vitality of which might be impaired—e.g., those of alcoholics, diabetics, and arterio-sclerotics; and further in those tissues which immediately overlay bone with little subcutaneous tissue. Another point which he raised was that in this process tissue cells, both normal and abnormal, were undoubtedly damaged and that in so far as they were still in the dark as to the etiology of malignant disease greater care should be taken. He here quoted Ribbert that the proliferative power of the various component cells of a tissue is regulated by "tissue tension," there being in health a condition of equilibrium among the various tissue elements; any pathological disturbance of such an arrangement might conceivably lead to the weakening of some inhibiting power

on the part of the less resistant tissue elements, and that this weakening might lead to a vegetative proliferation of these elements with the result of the formation of a neoplasm. Time alone could prove this possible danger to be real or imaginary, and while not wishing to be considered an alarmist, he urged the necessity of carefully choosing cases and as carefully noting the results. Preliminary antiseptic treatment of the skin was not generally carried out, but in view of the fact that many pathogenic bacteria could be exposed to very low temperatures without impairment of vitality Dr. Patterson considered that it would be profitable so to carry it out. The classes of cases in which he had used the method and obtained satisfactory results were: 1. Nævi of the pigmented mole and capillary types. 2. Certain cases of lupus vulgaris, though for the majority of cases of lupus he was doubtful of its value. 3. Lupus erythematosus, in which he had obtained very satisfactory results. 4. Rodent ulcer; small and soft rodent ulcers were satisfactorily treated by solid CO_2. He advocated in these the additional use of scraping with the curette in the frozen tissue under strict antiseptic precautions, and later treating the raw healing surface with the X rays. 5. Warts. The disadvantage here was the increase of time necessary for the application. 6. Hypertrophic scars and true keloids also reacted satisfactorily. Dr. Patterson concluded by pointing out the advantages of the method and its easy use, adding that in the latter there might lurk danger. The paper was illustrated by a series of cases.

Reviews and Notices of Books.

Hereditary Characters and Their Modes of Transmission. By CHARLES EDWARD WALKER, M.Sc., &c.; Director of Research in the Glasgow Cancer Hospital, &c.; Author of "Essentials of Cytology." London: Edward Arnold. 1910. Pp. 239. Price 8*s.* 6*d.* net.

THE appearance of this book, as well as that of two others noticed below, testifies to the increasing interest taken in the subject of heredity by workers and thinkers in many fields. The importance of this subject is scarcely greater than the difficulty of its study, and such an exceptionally lucid and thoughtful book as that now before us should meet with the welcome and command the consideration that it so fully deserves at the hands of all serious students. The author, already well known as an able worker in the field of cytology, emphasises, with justice, the importance of the study of cell phenomena in connexion with the problems of heredity, and devotes the first two chapters to a description, with good illustrations, of this aspect of the subject. The accounts given of current knowledge and of the author's own observations regarding the changes occurring in the fertilised ovum are remarkably clear. These chapters form an introduction to the rest of the book, which is written throughout with equal ability and clarity.

Although this work may certainly be regarded as an exceptionally good and critical compendium of the various views concerning heredity, and, as such, a highly instructive introduction to this study, it is specially marked by the setting-forth of a new theory concerning the "modes of transmission" of hereditary characters. The author states in the preface that, in attempting to apply recent discoveries, as well as experimental work upon cells, to some of these problems, he believes he has arrived at a satisfactory harmonising of the results of the Mendelian experiments with the observations of the biometricians. This, he says, has been done by showing that some parts of the cells involved in fertilisation are "distributed" in an alternative manner, while others simply divide in bulk. He thus puts forward a theory, dividing characters into "individual" and "racial," and attributing to each set of characters a different mode of "transmission." The so-called *individual* characters are transmitted, in the "Mendelian" or alternative manner, by the chromosomes; while the *racial* characters are blended and transmitted "by the potentiality of the whole fertilised cell."

It would be impracticable to enter fully within the limits of this review on the reasons which seem to throw some doubt on the soundness of this new hypothesis, and on the author's claim to have harmonised the results of the two biological schools which he mentions. However, a few difficulties and obscurities may be indicated. "Individual" characters are defined (on p. 184) as "either individual variations or characters inherited from a parent, which are not common to the race, but are confined to individuals that have inherited a variation from a near ancestor." This seems to be somewhat vague, and scarcely a definition in the strict sense, but rather a description of the meaning of the word as used by the author himself in setting forth his theory. Again, while holding that "individual" characters are recent, and that racial characters are ancient, the author has to admit that sex, which he regards as an individual character and as transmitted alternately, differs widely from other individual characters in this respect. Once more, the author in several places seems not to recognise any difference between "transmission" and "reproduction." Indeed, when discussing Mendelian views he suggests that the contention of Dr. Archdall Reid, that there is no real alternative inheritance in the case of "Mendelian" characters, but only alternative reproduction—or alternative patency and latency—is only a play on words. But the "character" of sex is not always produced "alternately," and an admittedly racial character may reappear in a cross when both parents lack this character; and thus a valid difference between inheritance and reproduction becomes apparent.

A very close agreement with the views and arguments of Archdall Reid, as set forth both in his earlier works and in his recent and important treatise on the "Laws of Heredity," may be noted in this volume. This is especially remarkable in Chapter IX., which deals with the Lamarckian view of the inheritance of acquired characters and the persistent misunderstanding or misrepresentation of "Darwinism" which pervades the writings of the present followers of Lamarck and Herbert Spencer. In many parts also of the chapter on Mendelism, and on the function of sex, as well as of the final chapter of conclusions, the author's line of argument is almost the same as that of Reid. In making this comparison we do not imply any disparagement of the extremely able and suggestive book which is the subject of this notice. The book bears every mark of independent thought and conviction. The author has evidently read widely and has made his own every conclusion which he has endorsed. He has produced a valuable contribution to the study of heredity, which will certainly take a serious place among writings on the subject, whether or not the special hypothesis which is set forth in it may fail to withstand the application of further tests.

Phases of Evolution and Heredity. By DAVID BERRY HART, M.D. Edin. London: Rebman, Limited. 1910. Pp. 259. Price 5*s.* net.

THE first five chapters of this book consist of short accounts and slight criticisms of some theories of heredity, leading up to a speculation on the origin and transmission of variations. In setting forth the speculation, which is termed "An Intrinsic Theory of Variation and Its Transmission," the author mainly relies on the observations and hypotheses of Mendelians, Mutationists, and Biometricians, and apparently takes no account of the views held by the majority of biologists who belong to none of these schools. In speaking of the inheritance of acquired characters, for instance, he seems to imply that all biologists, other than

those whose views he adopts eclectically as the foundation of his hypotheses, are "looking about for some mechanism that will make the actual somatic variations or injury causal in the germ-cells."

To put it briefly, the "theory" suggested by himself is that "the gametes, before combination to form a zygote, do not contain the complete outfit of determinants necessary to form an adult and its progeny"; that changes in the zygote make up the necessary complement; and it is these zygotic changes which produce the results known as "Mendelian." There is, according to him, a "propagative" and "somatic" part in each zygote, the former being the "primitive germ-cell mass" from which the future gametes will spring, while the latter gives rise to the body of the future individual. In the propagative part lie the determinants for the race; in the somatic part the determinants for the individual. In another place the author, in effect, sums up as follows his statements on Variation: the primitive germ-cells, which give rise to the gametes, arrive at the sexual gland without variation. In the gland they undergo variation in the determinants of the "unit characters," according to the Law of Probability. After the union of the gametes to form a zygote the "phenomena of Mendelism" arise, by which the unit characters are distributed in the zygote, again according to the Law of Probability. The author adds: "What biometricians may make of this speculation I do not know." What other biologists might make of it appears also a little problematical. While there is evidence in this book that the writer has read much and thought deeply round some of the problems of heredity, we cannot help missing a comprehensive grasp of the subject, such as would have given the critical power necessary to treat the various hypotheses and observations which he seeks to harmonise in the establishment of his own views.

The latter part of the book consists of more or less disconnected, though often interesting, essays.

The First Principles of Heredity. By S. HERBERT, M.D. Vienna. London: A. and C. Black. 1910. Pp. 199. Price 5*s.* net.

THE purpose of this book is to supply what is "desirable for the average intelligence to know" about heredity without assuming any previous knowledge of the subject on the reader's part. The author makes, therefore, no claim to originality, but he has achieved his stated purpose as well as could be expected considering the small space to which he has confined his compendium of various teachings on this very complex subject. The absence, however, from this book of sound critical leading must leave, we think, very indefinite impressions on the reader's mind, and we incline to the view that all those who really desire to understand the subject, or, still more, to pursue it further, should begin their study with one of the larger treatises, which deal more thoroughly and comprehensively with the problems of heredity.

The chapters on "Reproduction," "The Germ-Cells," "The Inheritance of Acquired Characters," and "The Inheritance of Disease," show that the author is well acquainted with the best literature on the subjects and deserve very high commendation. One pronouncement which the author makes in his final chapter seems to us to be dangerous doctrine, especially in a book which deals with problems of which few solutions are universally accepted. It is stated that "a science, in order to become a real science, must contain certain leading principles, serving at the same time as a unifying bond of the organised knowledge and *giving us working ideas for our guidance in practical life.*" Surely science is science still, in the full meaning of the word, even when inquiry duly conducted is unable to arrive at the goal indicated in this quotation. Scientific inquiry, as such, has no such goal, however imperative it may be for us to direct all practical action, as far as possible, on principles which are indicated and justified by science.

Practical Physiology. Edited by M. S. PEMBREY, M.A., M.D. Oxon. Third edition. Illustrated by 256 diagrams and tracings. London: Edward Arnold. 1910. Pp. xviii.-480. Price 14*s.* net.

FIVE years have elapsed since the second edition of this work was issued and eight since the first. Instead of five contributing authors there are six, and though the number of pages has been reduced from 503 to 480, the volume is a thicker one than its immediate predecessor. In the former editions the subjects were classed into four parts and were arranged as elementary and advanced. A much better method is adopted by keeping experimental and chemical physiology apart. Wisely, we think, the experiments on muscle and nerve have been reduced, and the observations which can be made upon man have been increased. A short contribution of eight pages on X rays for the investigation of motor functions of the alimentary canal is made by Dr. A. F. Hertz.

The chief changes are those of transposition and rearrangement of the subject matter. The first 50 odd pages are identical with those in the previous editions; 10 pages are transferred from the advanced part, a few pages being omitted, such as those dealing with isometric and paradoxical contraction and Pflüger's law, and the effects of some drugs, and the result is that 92 pages are given to nerve-muscle physiology instead of 106. To the circulation 79 pages are devoted instead of 72. The *a.-v.* bundle is figured, and a few additions are made in the text, while there are some omissions, such as cardio-pneumatic movements and the tortoise heart (Chapters XXV.–XLII.). Under the head of the Pulse we do not find an account of Pachon's sphygmometer, which seems to us a very sensitive instrument. Fig. 140 is named "the kymograph," while in the former edition it is given as "the Hürtle kymograph," perhaps a needful term as there are so many varieties of kymograph. About 25 pages are devoted to respiration, to which a few additions have been made. There is no very material change in the chapters on the central nervous system and the special senses. From the latter there are a few commendable omissions.

About 200 pages are devoted to "Physiological Chemistry," some of the chapters previously assigned to Dr. J. J. R. Macleod being relegated to Dr. Martin Flack. The chapters on carbohydrates and proteins are brought up to date. The photographic spectra of hæmoglobin appear to be omitted, while new chapters are added on inorganic acid radicles of urine, on lactic acid (J. H. Ryffel), and on hæmolysins and precipitins. Milk can hardly be called an "opalescent solution" (p. 326). In the experiment (p. 332) it might be well to state which "salted plasma" is used, and the clotting of blood might be compared with that which occurs in muscle as well as with milk clotting. In the chapter on blood we do not find Katyama's test for HbCO, which, whatever its precise value, gives a very striking reaction; nor is Rubner's test included. The bands of Soret in the ultra-violet spectrum seem to be omitted. It would be useful to add a simple test for the detection of iron in the bile. For the somewhat dubious statement in the second edition "a diet containing it (proteid) alone can serve as an efficient food" (p. 209), we have "a diet containing protein and salts alone can serve as an efficient food." Additions have been made here and there to the chapters on digestion; "Grutzner" on p. 386 should be "Grützner." Autolysis seems to be omitted.

This edition will certainly prove as useful to students as its predecessors, and our little criticisms, which may seem meticulous, are made with the idea that a fourth edition will be called for, when the indications furnished may be serviceable. The price is raised from 12*s.* 6*d.* to 14*s.* net.

Military Hygiene. By ROBERT CALDWELL, F.R.C.S. Edin., D.P.H., Lieutenant-Colonel, R.A.M.C.; Specialist Sanitary Officer, Pretoria, Potchefstroom, and Natal; late Specialist Sanitary Officer, Western Area, Southern Command, &c. Second edition. With 80 Illustrations. London: Baillière, Tindall, and Cox. 1910. Pp. 580. Price 12*s.* 6*d.* net.

THE reception accorded to the first edition of this book has encouraged the author to hope that a second venture on a somewhat more ambitious scale might not be out of place. Lieutenant-Colonel Caldwell, while addressing the present edition primarily to officers of the Royal Army Medical Corps, expresses a hope that it may also prove useful to all branches of the service, and therefore conveys his information in the simplest language consistent with the subject.

The book opens with a chapter on "The Work of the Microbe" in relation to armies in the field, and many interesting references are made to the prevalence of disease from early times down to the South African war. Then follows a dissertation on immunity which acts as an introduction to the discussion of the subject of inoculation against enteric fever by antityphoid vaccine, the method of preparation and dosage of the vaccine, and some statistics are quoted to prove the advantages of inoculation. Enteric fever, the relation of its propagation to camps, personal contact, food, carriers and other sources, form the subject-matter of the following chapter, which closes with a further list of statistics connected with the results of antityphoid inoculation. The next seven chapters are devoted to the discussion of the following diseases—dysentery and diarrhœa, malaria, plague, pneumonia, contagious ophthalmia, dengue, jaundice, cholera, Malta fever, barrack-room sore-throat, and parasitic diseases. The portion dealing with animal parasites will prove useful, notwithstanding that the descriptions of the parasites themselves and their ova have been purposely omitted, the author assuming that his readers have a sufficient knowledge of their characteristics. Sanitary organisation is the subject matter of Chapter XII., and the medical departments of both the United States and our own army come in for a fair amount of comment. Stress is laid on the necessity of including the principal medical officer of a division on the staff of the general officer commanding; at present he is not included, and we have before now pointed out that the omission is regrettable. The physical training of the soldier is dealt with in the succeeding chapter; the methods of carrying equipment are well illustrated by clearly produced photographs of soldiers in the "marching out" kit of different armies, including our own. In the next chapter sanitary matters connected with the maintenance of good health amongst soldiers, such as water, air, food, clothing, &c., are treated in detail. The author in passing (p. 288) very rightly draws attention to the unsound procedure of the authorities in detailing any available medical officer, without any regard to particular qualifications, for boards for the purpose of inspecting and reporting upon the sanitary condition of newly-constructed quarters: an officer skilled in sanitary science should rather be selected.

The sections dealing with meteorology, climate, and geology are all well compiled, and a geological map of the United Kingdom (in colours), which has been very creditably prepared by Messrs. Longmans, Green, and Co., is an attractive feature which may be of service in the selection of camping grounds. Chapters XXV.–XXVII. deal with the methods of sick transport (special prominence being given to the methods of Colonel H. G. Hathaway, A.M.S.), routine duties of medical officers, infectious diseases, alcohol, buildings, and tents, all these subjects being treated in an interesting way and well illustrated by diagrams and photographs. The last chapter, on Physical Degeneration in its Connexion with the Army, containing as it does a contrast between military and civil life, forms a good conclusion to a good book.

Lieutenant-Colonel Caldwell is to be congratulated on his painstaking efforts; he has evidently worked hard to collect facts connected with the hygiene of the soldier, and the references he makes to the published writings of his brother officers indicate a generous loyalty to their work, while greatly adding to the value of his own, which thus affords a ready reference to original sources. From his own experiences the author is able to add to the value of these writings by personal observations and views. The book is well indexed; great care has apparently been exercised in the reproductions of diagrams and photographs, the latter especially being excellently reproduced.

Urgent Surgery. By FÉLIX LEJARS, Professeur Agrégé à la Faculté de Médecine de Paris. Translated from the sixth French edition by WILLIAM S. DICKIE, F.R.C.S. Eng. With 20 full-page plates and 994 illustrations. Vol. II. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Bristol: John Wright and Sons, Limited. New York: William Wood and Co. 1910. Pp. 580. Price 25*s.* net.

THE favourable opinion which we expressed in reviewing the first volume of this excellent translation of Lejars' well-known work on the surgery of emergencies is fully confirmed by the examination of this, the second and concluding volume. It deals first with the genito-urinary organs, and includes such subjects as curetting the uterus, renal decapsulation, rupture of the urethra, and the treatment of distended bladder. The surgery of the rectum and anus and of strangulated hernia follows. Dislocations naturally are described and fractures also, and the volume ends with urgent amputations, wounds of tendons and joints, and acute osteomyelitis.

The prodigality with which the illustrations are provided enhances greatly the value of the work to the reader, for suitable diagrams or illustrations frequently explain much more clearly than many words. We gladly bear witness to the value of the work and wish it in its English dress the success which the original has attained.

JOURNALS.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLI., Nos. 3 and 4. London: C. F. Clay, Cambridge University Press. Nov. 9th, 1910. Price 8*s.* 6*d.*—The articles contained in these numbers are: 1. The Secretion of Urine, by Joseph Barcroft and Hermann Straub, from the Physiological Laboratory, University of Cambridge. The authors find that the diuretics they have studied fall into two groups—(1) those which produce urine without alteration in the gaseous exchange of the kidney (Ringer's solution and NaCl in hyper- and hypo-tonic solutions); and (2) those which cause increased gaseous exchange (urea, caffeine, sodium sulphate), to which may be added phloridzin. They find also that clamping the kidneys for 15 minutes after washing out the vessels with Ringer's solution does not abolish its power of secretion. 2. On the Governing Influence of Environment on Enzymic Action, by F. W. Pavy, M.D., LL.D., F.R.S., with the collaboration of H. W. Bywaters, D.Sc., Ph.D., F.I.C., from the Physiological Laboratory of the University of London, South Kensington.

The authors show that the inverting power of an aqueous extract of yeast is increased ten to fifteenfold by the addition of a boiled extract of yeast, which is essentially due to the acidity of the boiled extract. After desiccation treatment with alcohol or grinding up with kieselguhr greatly enhanced enzymic action as shown in the aqueous extract. 3. The Mode of Union of Certain Poisons with Cardiac Muscle, by H. M. Vernon, from the Physiological Laboratory, University of Oxford. The effects of perfusing the tortoise heart with oxygenated Ringer's solution, containing alcohol, ether, hydrocyanic acid, sodium chloride, and formaldehyde, are given. 4. The Action of Atropine, Pilocarpine, and Physostigmine, by Arthur R. Cushny, M.D., F.R.S., from the Pharmacological Laboratory, University College, London. 5. The Composition of the Gases of the Blood in Chloroform Anæsthesia, by G. A. Buckmaster and J. A. Gardner, from the Physiological Laboratory, University of London. 6. Visual Phenomena Connected with the Yellow Spot, by F. W. Edridge-Green, M.D., F.R.C.S., Beit Medical Research Fellow. 7. The Influence of Carbohydrate and Fat on Protein Metabolism, by E. P. Cathcart and M. Ross-Taylor, University of Glasgow. This article gives the effect of phloridzin glycosuria. These numbers contain also the proceedings of the Physiological Society for Oct. 15th, 1910.

ST. MARYLEBONE GENERAL DISPENSARY.—A festival dinner to commemorate the 125th anniversary of the foundation of this charity was held at the Langham Hotel on Nov. 24th. The company consisted of nearly 100 friends of the dispensary, with Lord Howard de Walden in the chair. The list of speakers included Sir R. Douglas Powell, Mr. Andrew Clark, ex-members of the medical staff, the Rev. Dr. Morrison, rector of St. Marylebone, Mr. Ernest R. Debenham, the Mayor of St. Marylebone, Mr. James Boynton, M.P., Lieutenant-Colonel Hon. G. H. Windsor Clive, Dr. A. G. Auld, and Dr. Eric Pritchard. The long and useful history of the dispensary was strongly emphasised by Lord Howard de Walden, who remarked that in many ways dispensaries, such as the St. Marylebone General Dispensary, had claims on the public equal to those of the larger general hospitals, for they dealt with the prevention of disease or its treatment while it was still capable of cure, and in this connexion he referred to the invaluable work done by the dispensary in the treatment of tuberculous patients and in the prevention of infant mortality by the operations of the infant consultations carried on at the institution. The funds collected as the result of this special appeal amounted to over £1200.

GLASGOW UNIVERSITY CLUB OF LONDON.—Lord Curzon of Kedleston, Lord Rector of the University of Glasgow, presided at a dinner of this club at the Gaiety Restaurant, Strand, on Nov. 25th and proposed the toast, "The University and the Club." He said that the main source of pride to a Lord Rector was that during his term of office he felt he was brought into contact with an important section of the youth of the country and was able to learn something of the ideals and aspirations by which they were moved. They heard a good deal nowadays of the distinction between the old and new universities. There was no rivalry between them; they each gave a system of education which was necessarily different. The older universities of England could not cover the whole field, and those who spoke for them regarded with pleasure the creation of new universities. There was no such contrast and diversity of function in Scotland, however, where the four ancient universities held the field in an unassailed and impregnable position. The toast of "The Guests" was proposed by Sir Donald MacAlister and responded to by Lord Lamington and Mr. Harold Cox. Among those present were Canon Hensley Henson, Sir Thomas Barlow, Sir Henry Craik, Mr. G. L. Craix, Sir John Batty Tuke, Dr. D. N. Knox, Sir Charles Ball, Dr. George Heron, the Hon. N. C. Rothschild, Sir David McVail, Sir John Moore, and Sir Christopher Nixon.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, NOV. 23RD.

THE Council resumed its sittings at its offices, 299, Oxford-street, W., Sir DONALD MACALISTER, the President, being in the chair.

Penal Cases.

The whole of the sitting was occupied with the hearing of penal cases.

The first charge against a practitioner was dismissed.

The second case to be considered was that of James Dalziel, registered as of Auckland, New Zealand, Lic. R. Coll. Phys. Edin. 1867, Lic. R. Fac. Phys. Surg. Glasg. 1867, who had been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you unlawfully used an instrument or other means with intent thereby to procure the miscarriage of one Jennie Barraclough, of which offence you were on August 14th, 1907, convicted at Auckland, New Zealand, and sentenced to four years' imprisonment. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Mr. DALZIEL did not appear, nor was he represented.

Mr. WINTERBOTHAM (the solicitor to the Council) said that this was not a case of conviction within the British Islands. The result was that the case had to be dealt with as one of infamous conduct in a professional respect. He handed in a certificate of conviction.

The PRESIDENT announced the decision of the Council as follows: The Council have judged James Dalziel to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of James Dalziel.

The Council then considered the case of George Gray Wilson, registered as of 23, Duncan-terrace, Islington, N., Lic. R. Coll. Phys. Edin. 1898, Lic. R. Coll. Surg. Edin. 1898, Lic. Fac. Phys. Surg. Glasg. 1898, who had been summoned to appear before the Council on the followihg charge, as formulated by the Council's solicitor:—

That you abused your position as a medical man by committing adultery with a Mrs. Moore, with whom you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated March 15th, 1910, in the case of Moore *v.* Moore and Wilson, in which you were the co-respondent. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Mr. Wilson appeared in person and was accompanied by Mr. E. W. Fordham, his counsel.

Mr. WINTERBOTHAM (the solicitor to the Council) briefly indicated the circumstances in which the charge came to be brought against Mr. Wilson. The case was brought to the notice of the Council through the proceedings in the Divorce Court, and the fact of the adultery after its decree could not be denied. The question with which the Council had to deal turned on whether there was the professional relationship of doctor and patient existing between the parties. Mr. Wilson had been employed as surgeon on board vessels of the P. and O. Company. He first met the lady and her husband on a voyage from Aden to Bombay, and he had been medical man on the vessel in which she had returned to England. He (Mr. Winterbotham) would contend—although this was disputed by Mr. Wilson—that he in his ordinary course of duty attended the lady, advised treatment, and supplied medicines. It was admitted that he had had her removed for a time to the hospital cabin which was under his control.

Dr. T. H. A. CHAPLIN, medical inspector of the P. and O. Company, who gave evidence, stated that the lady's name did not appear in the book of the medical man as having been ill. A surgeon in the service of the company was paid by it. He was not allowed to ask for a fee from passengers whom he attended. If anyone out of gratitude offered a surgeon a fee he was not prohibited from taking it.

The PRESIDENT asked whether there was anything in the regulations of the company to the effect that the medical man was to be regarded in a professional relation to all on board.

Dr. CHAPLIN: No. That is a point on which I would like to have a ruling.

Two other witnesses were heard in relation to the allegations on which the charge was based.

Mr. GEORGE GRAY WILSON gave evidence on his own behalf. He stated that he did not make arrangements that the lady would return in the same vessel as he. He never attended her or her husband in a professional way. There never had been any professional relationship between him and the lady at any time. She had been accommodated in the hospital cabin on account of the heat in her own cabin. He had not visited her there, and he emphatically denied that there had been improper relations whilst he was the ship's doctor.

Mrs. MOORE also gave evidence and denied that there had been the professional relationship of medical man and patient between her and Mr. Wilson.

Mr. FORDHAM then addressed the Council on behalf of Mr. Wilson and argued that the professional relationship did not exist. If the Council were to hold that every passenger and every member of the crew was a patient of the ship's medical man it would be a most dangerous precedent. The law regarded with great jealousy the relation between medical man and patient, particularly as regarded gifts. The rule was particularly stringent, because of the fear or presumption that there might be undue influence as between medical man and patient. If it was to be held that every member of a ship's company and every passenger was a patient of the ship's surgeon the presumption would have a very far-reaching effect. He would venture to submit that the rule could only be intended to apply to the actual cases where the ship's surgeon was in actual attendance on persons who were suffering from illness. A Christian Scientist, for example, might be on board ship and would object to call in the assistance of a ship's surgeon as against his belief. Could it be said that in such a case the relationship of medical man and patient would exist? He (Mr. Fordham) would submit that the relationship did not exist in this case. As a matter of fact, there was nothing to show that the lady was a patient of Mr. Wilson. Indeed, both of them denied it. In these circumstances he asked the Council to dismiss the charge against the accused practitioner.

The Council then adjourned.

THURSDAY, NOV. 24TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W., Sir DONALD MACALISTER, the President, in the chair.

Penal Cases.

The Council considered in private the case of George Gray Wilson, which had been heard on the previous day.

The PRESIDENT, after the public had been readmitted, said: Mr. Wilson, the charge against you was:—

That you abused your position as a medical man by committing adultery with a Mrs. Moore, with whom you stood in professional relationship, of which adultery you were found guilty by the decree of the High Court of Justice in the case in which you were the co-respondent. I have to inform you that the Council have judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of George Gray Wilson.

The Council then took up the consideration (adjourned from May 27th, 1910) of the case of James Forrest, registered as of 60, Gordon Mansions, Gower-street, London, W.C., M.B., Bac. Surg. 1897, Univ. Edin., who had been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you have associated yourself as a member of its committee and also as one of its surgeons with an institution called the "Eye and Ear Clinique," and also the "National Eye Hospital," and the "National Eye, Ear, Nose, and Throat Hospital" of 123, Oxford-street, London, W., which advertises by pamphlets and in the public press for paying patients. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Dr. FORREST did not appear nor was he represented by solicitor or council.

The British Medical Association, who were the complainants, were represented by Mr. Cox, assistant secretary to the ethical committee, who was accompanied by Mr. Hempson, solicitor.

The PRESIDENT asked those members of the Council who were not present when the case was previously before the Council, and also those members who were also members of the British Medical Association, to retire from the hearing of the case.

This request was complied with by the members concerned.

Mr. BODKIN (the legal assessor) said that this case was before the Council on May 26th last. In May Dr. Forrest gave a considerable amount of evidence and answered questions put by the Council. In the course of these questions it was thought desirable that the books and the minute books of the "Eye and Ear Clinique" should be produced before the Council. Mr. Washington, the solictor of Dr. Forrest, agreed to have an adjournment until the next day in order that he might bring forward some of the members of the committee of the institution in question and produce the books for the inspection of the Council. Accordingly, there was an adjournment until the afternoon of the following day. Mr. Washington said that he was not sure that he would be able to get his witnesses to the Council at that time. Before that time came Mr. Washington had ceased to act on behalf of Dr. Forrest. When the case came again before the Council Dr. Forrest did not attend, nor did anyone on his behalf. Then came the discussion as to what steps should be taken, and it was decided that the matter should stand over until the next session.

The SOLICITOR to the Council intimated that a letter, addressed to the General Medical Council, and dated Nov. 15th, had been received from Dr. Forrest as his defence to the charge. It was in the following terms:—

I enclose documentary testimony in proof of my statements made before you, at your last meeting, with regard to the administration of the Eye and Ear Clinique. As the case was concluded at the last meeting and judgment was postponed solely for the production of the above documents, I do not propose attending personally, but I beg leave to controvert certain statements made by the prosecution.

Their solicitor stated that no inquiries were made with regard to the financial position of the patients attending the Clinique. This is true; but we contend that such inquiries do not prevent abuse, and so offer no protection, for a patient who has determined to prostitute his sense of truthfulness to gain some slight monetary advantages will not be deterred by the inquisitorial methods adopted by many hospital authorities.

The plan in vogue at the Clinique was only resorted to after much deliberation, and consists in an exposition—by the nurse—to each patient of the objects of the institution, and particularly of the class to which it appeals.

With reference to T. W. Tyrell's account of his visit to the Clinique, I wish you to note that his description of the conversation he had with the nurse is both contradictory and incongruous. His statement that a copy of THE LANCET was lying on the table is a lie. It is unnecessary to refute in detail his narration of my conversation with him, as most of it is irrelevant to the case; but his departure from the truth is perhaps largely attributable to a desire to present a good case for his employer, who, I note, is the solicitor for the prosecution.

With regard to our advertisementss to which exception has been taken, we only followed the precedents set by other institutions. I enclose an incomplete list of those which advertise either overtly or covertly for paying patients, and a perusal of their reports (which I also submit) shows that the money derived from the payments of patients is from 60 to 100 per cent. of the total income of the institution. As such notices have appeared regularly for years, the inference that the underlying principles were approved by the medical authorities appeared to us the only logical one, especially as the advertisements appear in those papers which appeal chiefly to the working classes. We inserted a public notice in the press once only, and then I am charged with infamous conduct in a professional sense; yet these other institutions are advertising regularly every week with impunity. These gross anomalies which are allowed to prevail with regard to public notices in the press have been largely created by the inactivity or tacit approval of the prosecuting body, who affect to protect the interests of the medical practitioner; and so strongly do I feel in relation to these irregularities that their continuance will compel me, from conscientious motives, to have my name voluntarily erased from the Register.

In conclusion I reiterate that if my conduct be infamous, then many other men on the staff of various London institutions ought to be arraigned before you on the same charge. JAS. FORREST.

The following statutory declaration was also read by the Solicitor:—

IN THE MATTER OF THE COMPLAINT AGAINST JAMES FORREST, M.B., F.R.C.S.E., OF THE EYE AND EAR CLINIQUE, LONDON.

Statutory Declaration by Alfred Ernest Yates, dated Nov. 15th, 1910

I, ALFRED ERNEST YATES of 30, Brown-street, Manchester, do solemnly and sincerely declare as follows: I provided funds (without interest) for the foundation of the above institution, and furthermore guaranteed it against loss for a period of five years. The administration of the Clinique and the management of finances are under the control of an honorary committee, whose addresses are as follows:—

A. E. YATES (Engineer), 30, Brown-street, Manchester.
ELLEN MITCHELL (Independent), South Shore, Blackpool.
F. WESTCOTT (Shipper), Thorners Chambers, London.
P. PHILLIPS (Tobacco Manufacturer), Metherall-gardens, W.
JAMES FORREST (Surgeon), 1, Duke-street, Manchester-square, London.
W. HARRISON (Stockbroker), Gresham House, E.C.

The late Dr. RAMMAGE was also a member.

Amongst the many resolutions passed by the committee the following two are germane to this case:—

1. That any excess of income over expenditure shall be devoted in the first place to the provision and full equipment of an in-patient department, and afterwards to the repayment of the donor.

2. That no salary be given to the surgeons for their services until the donor be reimbursed, and that such salary shall not exceed £100 per annum.

This small honorarium was not intended to represent an adequate remuneration for the surgeons' services, but given with the view of excluding purely honorary service.

This closed the case for Dr. Forrest.

The PRESIDENT announced the decision of the Council as follows: I have to announce that the Council have judged James Forrest to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of James Forrest.

The Council took up consideration of the case of Herbert Llewellyn Porteous, registered as of Wickham Grange, Chalford, Gloucestershire, Mem. R. Coll. Surg., Eng. 1898, Lic. R. Coll. Phys., Lond. 1898, who had been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you were on your plea of guilty convicted on June 21st, 1910, at the Gloucestershire Assizes before the Honourable Mr. Justice Lawrence, of certain misdemeanours, and were ordered to enter into your own recognisances in the sum of £10 to appear to receive judgment upon your said conviction if and when called upon so to do, such misdemeanours being contraventions of the provisions of the Lunacy Act, 1890: (*a*) in that you in December, 1909, and in January, 1910, whilst you were the medical attendant of two lunatic single patients named Evelyn Mary Whish and Irene Henrietta Anne Linthwaite, residing in the house of one Sarah Fisher, did contrary to Orders dated April 10th, 1907, made by the Lunacy Commissioners in respect to such patients under the Lunacy Act, 1890, and the rules made thereunder to the effect that such patients should be visited by you as such medical attendant once in every six weeks, and that you should make in the medical journals respectively relating to such patients entries relative to their condition at such visits, did make default in complying with such Orders; and (*b*) further in that you being the medical attendant of the said Evelyn Mary Whish and subject to the requirements of the said Order did unlawfully and knowingly on Dec. 24th, 1909, make in the medical journal relating to her a false entry implying that you had then visited her and had made the said entry as the result of your personal examination of her, contrary to Section 318 of the Lunacy Act, 1890; and (*c*) further in that you being the medical attendant of the said Evelyn Mary Whish and Irene Henrietta Anne Linthwaite, and subject to the requirements of the said Orders, did unlawfully and knowingly on Feb. 3rd, 1910, make certain false entries and certain wilful mis-statements of material facts in the medical statements relating respectively to the said patients, such false entries and mis-statements implying that you had on the said Feb. 3rd, 1910, seen and examined the said patients, whereas you had not then seen and examined the said patients, contrary to Sections 317 and 318 of the Lunacy Act, 1890; and (*d*) further in that you failed on Jan. 10th, 1910, to make a report as to the state of bodily and mental health of each of such patients to the said Commissioners. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Mr. Porteous appeared in person, and was accompanied by Mr. Hempson, solicitor.

Mr. WINTERBOTHAM made a statement to the Council concerning the particulars of the charge.

Dr. COUPLAND, a Commissioner in Lunacy, was called as a witness. He said that the reason why the Commissioners in Lunacy did not think it incumbent on them to bring the case under the notice of the Council was because although the breach of the law was grave and might have had serious consequences, Mr. Porteous had pleaded guilty and the circumstances under which the offence was committed showed that it was not done wilfully, but at the instigation of another. The conduct of Mr. Porteous showed that he did not realise his personal responsibility to the patients. However, the Commissioners thought that taking the circumstances into consideration it would be vindictive on their part to take the further step of reporting the case to the General Medical Council. At the same time the Commissioners hoped that the prosecution would have the effect of making all members of the medical profession recognise that their duties were of a most responsible nature.

Answering the President, Dr. COUPLAND said that there might be cases where the Commissioners themselves would think it incumbent to take a case before the Council.

Mr. PORTEOUS gave an assurance to the Council that in future he would do everything in his power to give no cause for complaint on professional grounds.

Mr. HEMPSON submitted to the Council testimonials from local members of the medical profession, and gentlemen of standing in the neighbourhood in which Mr. Porteous practises, testifying to the high regard and esteem in which he was held. Mr. Hempson went on to say that the facts in this case were beyond dispute. Mr. Porteous had not sought in any way to withhold from the Council the full facts of the case as known to him. Dr. Coupland had given unexpected testimony towards the defence in this case. He said that he would have considered it hard and harsh to have reported the matter in order that proceedings might have been put on foot. He (Mr. Hempson) would submit that it was a hard case. Mr. Porteous had not made a single penny out of what he did, and fortunately no harm was done by his errors. Mr. Justice Lawrance considered that the case showed errors of judgment rather than acts of design. He therefore permitted Mr. Porteous to be discharged with kindly words of admonition, and assuring him that if there was nothing against his conduct in the future he would hear nothing more in the future.

The PRESIDENT announced the decision of the Council as follows: Mr. Porteous: The Council has found the conviction alleged against you in the notice proved, but it has not decided to pronounce judgment on the conviction at this meeting, but you will be called upon to appear before it at the May session on a day of which notice will be given you, when you will be required to produce evidence as to your conduct in the interval.

The Council proceeded to the consideration (adjourned from May 27th, 1910), of the facts proved against Edward Joseph Regan in regard to whom the Dental Committee, at its meeting on Monday, Nov. 21st, 1910, drew up a supplementary report. In the course of the report it was stated that Mr. Regan had attended personally and presented as evidence his own oral statement, but produced nothing in support of it.

At the close of the proceedings on May 27th, 1910, the PRESIDENT, addressing Mr. Regan, said: "Mr. Regan: The Council have considered the facts proved in the report of the Dental Committee but have not proceeded to pronounce judgment in your case, and have postponed the further hearing of your case till the November session, when you will be required to produce evidence as to your conduct in the interval, with special reference to your having ceased all relations with unqualified practitioners and advertising."

The complainants were the British Dental Association, represented by Mr. R. W. Turner.

Mr. REGAN attended and addressed the Council on his own behalf. He said that he had done his best to remove the cause of complaint against him, and he wished, if his name was permitted to remain on the Register, to continue to obey the rulings of the Council.

The PRESIDENT announced the decision of the Council as follows: "Edward Joseph Regan: I have to announce that on the facts found in the report of the dental committee you have been judged to have been guilty of infamous or disgraceful conduct in a professional respect, and that the Registrar has been directed to erase from the Dentists Register the name of Edward Joseph Regan.

The Council then directed its attention to the case of Alexander Peel Patterson, in regard to which the Dental Committee had made a report. In that report it was stated that the committee found that the following facts were established by the evidence:—

The said Alexander Peel Paterson was registered in the Dentists Register on Oct. 14th, 1878, as "In practice before July 22nd, 1878." His address in the Register for the current year is 63, Bradshawgate, Bolton. The said A. P. Patterson admitted that the four persons mentioned in the notice of inquiry are in his employ and are all unqualified, but stated that he has given all of them notice and in future intends to employ no unqualified persons. He further stated that the circular complained of was issued by him and had been in use for about 14 years, that with this exception he has never advertised, that he had discontinued the circular, and he undertook not to advertise again. The said A. P. Patterson has employed collectors who have distributed the said circular at their discretion, and if any practice resulted it would be of advantage to the collectors. The said A. P. Patterson stated the particulars in which he considered his system of dentistry to be superior to others. The said A. P. Patterson never saw Mrs. Clarke. None of his unqualified assistants know the constituents of the eucaine used in the practice. Their instructions are to use it carefully, not to waste it, and not to exceed two syringefuls. They have no instructions as to examining the heart, and they are not capable of doing it.

Amongst the evidence before the committee were depositions of witnesses taken touching the death of one, Mary Ann Clarke.

Mr. Patterson attended and was accompanied by his counsel, Mr. Barrington Ward.

The British Dental Association were the complainants and were represented by Mr. W. R. Turner.

Mr. BARRINGTON WARD addressed the Council on behalf of Mr. Patterson and said that his client did not know what he was doing was wrong. Clarke's case was that of a woman who died after dental treatment. There was no undue injury present and the cause of death was apoplexy. His client gave a most solemn undertaking that he would not employ

any unqualified man so as to allow that unqualified person to take part in any dental operation.

The PRESIDENT in addressing Mr. Patterson said: I have to announce that on the facts found in the report of the Dental Committee it has been proved that Alexander Peel Patterson has been guilty of infamous or disgraceful conduct in a professional respect, and that the Registrar has been directed to erase from the Dentists Register the name of Alexander Peel Patterson.

Examinations for the Services.

The report by the Examination Committee on the returns as to examinations for the services received since the last session of the Council was received.

The Apothecaries' Hall, Dublin.

The reports by the Examination Committee on the Final Examinations of the Apothecaries' Hall, Dublin, held in July and October, 1910, were also received.

The Assistant Examiner to the Society of Apothecaries.

On the motion of Mr. NORTON it was agreed that the temporary appointment of Mr. V. Warren Low, F.R.C.S. Eng., as Assistant Examiner to the Society of Apothecaries of London during the illness of Mr. Collier, which was sanctioned by the Executive Committee, be extended till such time as Mr. Collier might be able to resume his duties.

An Admission to the Medical Register.

The Council agreed to adopt the recommendation of the English Branch Council that Mr. Lewis Fabien should be registered. Mr. Lewis Fabien, Mem. R. Coll. Surg. Eng. 1876, is a medical practitioner entitled to be registered under the Medical Act (1858), but who neglected to effect such registration until after the "appointed day" (June 30th, 1887) under the Medical Act (1886).

Mr. FABIEN in making his application for registration supplied a statutory declaration giving the reason why he omitted to register before the Medical Act (1886) came into force—viz., that immediately after qualifying he proceeded to the colony of Trinidad, where he joined the Government Medical Service, and where he had been in regular practice ever since.

The Anæsthetics Committee.

The report of the Anæsthetics Committee was received and entered on the minutes, but discussion of the recommendations of the committee was deferred until a convenient opportunity later in the session.

The Council adjourned.

FRIDAY, NOV. 25TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was again in the chair.

Charge against Medical Man Dismissed.

The Council took up consideration of the case of William Peart-Thomas, registered as of 21, Portman-street, London, W., M.B., Mast. Surg. 1891, M.D. 1898, Univ. Edin., who had been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you have by your presence, countenance, advice, assistance, or coöperation, knowingly enabled an unqualified and unregistered person—namely, one Andrew Miller—to attend and treat patients as if he were duly qualified and registered. And that you have by your presence and coöperation with the said Andrew Miller, whom you knew to be an unqualified and unregistered person, during the course of his treatment of certain patients, enabled the said Andrew Miller to attend and treat such patients under such circumstances, and with the intention that in the event of the death of any of such patients, you should be in a position to give certificates of death in respect of them as if you were the medical practitioner who had been really in responsible attendance upon them. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant was Dr. Hugh Woods, acting on behalf of the London and Counties Medical Protection Society.

Dr. Peart-Thomas appeared, and was accompanied by his counsel, Mr. R. W. Turner.

Dr. WOODS explained to the Council the grounds on which the complaint was made. He said that in August, 1909, the Duke of Manchester became interested in the mode of treatment by one Andrew Miller, a man without medical qualification and registration, who professed to cure the disease of phthisis. In September, 1909, Mr. Miller came to this country to demonstrate his treatment under the auspices of the duke. To this end Miss Dempster, a hospital nurse with a nursing home in Upper Montagu-street, was approached with a view to her allowing some patients to undergo treatment by Mr. Miller there. This lady refused to allow this unless a properly qualified medical man was in charge. Dr. Peart-Thomas ultimately agreed to take charge. His duty, it was alleged, was to stop the treatment if dangerous symptoms supervened, and it was further alleged that in the event of the death of any of the patients he would be in a position to give a death certificate. It was contended that the action of Dr. Peart-Thomas in regard to this matter laid him open to the charge now made against him. Dr. Woods proceeded to read extracts from notes of evidence given in the county court with regard to the claim of Dr. Peart-Thomas for professional fees.

Mr. TURNER objected to the reading of these notes on the ground that they were neither official nor were they full and accurate.

The PRESIDENT said that the Council would keep in mind the character of the notes, and would only accept them subject to correction.

The Duke of Manchester was called as a witness.

Sir CHARLES BOXALL, his solicitor, stated that the duke did not wish to take any part in advancing the charge. He was quite prepared to assist the inquiry, but he was not a party to any attack on Dr. Peart-Thomas.

The Duke of MANCHESTER, in the course of his evidence, stated that so far as he was concerned in this matter he considered that everything was being done under medical supervision from the fact that a very highly respected committee of medical men had been taking a scientific interest in the matter. All that he had got Mr. Miller to come to this country for was to get his treatment tested by thoroughly scientific methods. When Dr. Peart-Thomas was brought in the contingency of his having to give a death certificate was far from his (the duke's) mind. He could not say if the matter was even mentioned. He understood that Dr. Peart-Thomas was to see that nothing dangerous took place, and to stop the experiments if anything like death was likely.

Dr. WOODS: Did he interfere with Mr. Miller's treatment.

The Duke of MANCHESTER: I am not quite sure.

Cross-examined by Mr. TURNER, witness said that he got a committee of English medical men to interest themselves in the treatment. They knew the nature of the drug. His idea was that Dr. Peart-Thomas should be a check, if necessary, against any dangerous treatment.

This closed the case for the complainants.

Dr. A. C. LATHAM was then called as a witness by Mr. Turner. He said that the duke came to him in September, 1909, and told him that Mr. Miller's treatment had been successful in cases of consumption. He also mentioned his desire to have it tested. Mr. Miller was prepared to tell what the treatment was, and if he was successful he would take care that every medical man should have the use of it. He told the duke that the best way to test the treatment was to go to the Brompton Hospital and ask those in authority there to do it. Mr. Miller objected because his nurse would not be admitted to the hospital. Dr. Latham told the duke that he and other medical men were prepared to investigate any cases brought to them. They would see their condition before and after treatment and would report to the duke. He (Dr. Latham) said that it was necessary that there should be a medical man in attendance, and he told Miss Dempster not to take the cases in until she had an assurance that there would be a medical man in attendance.

Mr. TURNER: So far as you know, was Dr. Peart-Thomas taking charge of these cases?

Dr. LATHAM: I was under the impression that Dr. Peart-Thomas was in charge of the cases as if he were a house surgeon in charge of them in a hospital.

In answer to the PRESIDENT, witness said that at the end of the treatment a report was presented to the Duke of Manchester. In the opinion of those medical men who made the report there was no evidence to encourage a more extended trial of the treatment.

Mr. F. F. BURGHARD spoke as a witness to Dr. Peart-Thomas's professional and private character.

Dr. PEART-THOMAS gave evidence on his own behalf. When he came to an arrangement with the Duke there was nothing said about death certificates. He knew the drug and the amount of the injection employed in the treatment. A nurse gave the injection. He had control of the patients. He was sent for on the temperature of one of them rising.

He approved of the regulation of their diet. So far as he could remember, the injections were used for four or five days, and in the case of one patient there was a second treatment. It would not harm the patient.

Mr. TURNER: Exercising your skill and judgment as a professional medical man, you permitted that to be done?

Dr. PEART-THOMAS: I did.

Did you exercise your judgment as a professional man before the injection was given?—I did.

Did you in any way submit to the directions of Mr. Miller in regard to this treatment?—No. Mr. Miller told me the drug and the former doses in America or somewhere. These patients were in a fit state to receive it. The drug was given by my orders by the nurse.

Is the suggestion true that you were "covering" Miller and enabling him to carry on a course of treatment?—There is no truth at all in that suggestion.

Dr. WOODS: Did you think the treatment detrimental to the patient?

Dr. PEART-THOMAS: No.

Do you now think it did good?—No; I do not think it did good.

Do you think it ineffective?—I think it was, after five or six weeks' watching.

What position did Mr. Miller occupy?—He was in the position of a nurse. He never examined the patients.

Were you in a position to prohibit the use of the drug?—I was in such a position. I was in charge of the cases in exactly the same way as a house surgeon.

Was Miller competent to prescribe?—I know nothing about Miller except I believe he is a doctor of dentistry. I know nothing of his capabilities.

Re-examined, witness regarded himself as medical practitioner in charge of cases.

Miss M. C. DEMPSTER, the head of the nursing home, gave evidence to the effect that Dr. Peart-Thomas was in full and complete charge of the patients.

Mr. TURNER addressed the Council on behalf of Dr. Peart-Thomas. He contended that there was not a shred of evidence of "covering" in any shape or form. Not a word could be said against the professional conduct of his client.

The PRESIDENT announced the decision of the Council as follows: Dr. William Peart-Thomas: I have to inform you that the decision of the Council is as follows: "That the facts alleged against William Peart-Thomas have not been proved to the satisfaction of the Council."

The Council adjourned.

SATURDAY, NOV. 26TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was again in the chair.

Report of the Pharmacopœia Committee.

On the motion of Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, the report of the Pharmacopœia Committee was adopted.

The report was in the following terms:—

From May 23rd, 1910, to Nov. 19th, 1910, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 545. The total number of copies sold in the year beginning Nov. 22nd, 1909, was 1094. The annual sale thus continues to be steady. Up to the present time 42 460 copies of the Pharmacopœia, and 4491 copies of the Indian and Colonial Addendum have been sold. The stock now in hand consists of 570 copies of the Pharmacopœia, together with 1843 copies of the Addendum. It will be necessary to print a fresh impression of the Pharmacopœia to meet the demands of the year now beginning, and the Committee recommend that the President be authorised to give orders for the work so soon as the publishers report that the present stock is approaching exhaustion.

The Committee appointed its secretary, Dr. Tirard, to take part, along with delegates sent by the British Government, in an International Conference held in Paris in June last. The purpose of the Conference was to discuss proposals for an international understanding on the subject of methods and standards of analysis in relation to food and drugs. Certain resolutions were arrived at, which are given in the report of Dr. Tirard hereto appended. These may have an important bearing on the analytical portions of the Pharmacopœia, and the Committee propose to give them due consideration in relation to the revision of the 1898 issue on which they are now engaged.

Meanwhile the thanks of the Council are due to Dr. Tirard for the valuable service he has thus rendered.

The PRESIDENT remarked that the approval of the report meant that the Council thanked Dr. Tirard for his services at the International Conference. It also meant that he (the President) was empowered to order more copies of the Pharmacopœia.

Students' Registration Committee.

A report was received from the Students' Registration Committee.

Public Health Committee.

Sir JOHN MOORE, in presenting the report of the Public Health Committee, said that the committee recommended that the applications of the University of Bristol, the National University of Ireland, and Queen's University of Belfast that their Diplomas in Public Health should be recognised for registration, should be acceded to. He mentioned that the application from the University of Wales, seeking recognition of the Diploma in Public Health issued by the University under its chartered powers, was considered by the committee. The consideration of this application was postponed, as the University had not yet obtained registrable powers for its degrees and diplomas under Act of Parliament. Sir John Moore moved:—

That the Diplomas in Public Health of the University of Bristol, the National University of Ireland, and the Queen's University, Belfast, be recognised for registration as additional diplomas.

Dr. NORMAN MOORE seconded.

The motion was agreed to.

On the motion of Sir JOHN MOORE it was also agreed—

That the legal bearings of a proposed amendment of the rules for the Diplomas in Public Health requiring registration, as well as the possession of a registrable qualification as a condition of admission to the examinations for these diplomas, be referred to the legal advisers of the Council for consideration and report.

The Anæsthetics Committee.

The report of the Anæsthetics Committee was considered. The committee had had before it a communication from the Privy Council addressed to the Registrar by Sir Almeric Fitzroy. Sir Almeric Fitzroy wrote:—

With reference to previous correspondence as to proposed legislation on the subject of anæsthetics I am directed by the Lord President of the Council to transmit to you a Memorandum and Draft Bill which have been submitted to the Home Secretary by Dr. Frederic Hewitt, M.V.O., and to ask you to be good enough to move the General Medical Council to favour his lordship with their observations thereon. I am to point out that the Draft Bill does not indicate the drugs or substances producing a state of unconsciousness which a dentist may be permitted to use.

The memorandum discussed at length various points which had arisen on the question of the administration of anæsthetics. The following was suggested as "a rough draft" of an anæsthetics Bill:—

1. Any person other than a legally qualified medical practitioner registered under the Medical Acts who shall administer or cause to be administered to any other person by inhalation or otherwise any drug or substance, whether solid, liquid, vaporous, or gaseous, and whether pure or mixed with any other drug or substance, with the object of producing a state of unconsciousness during any surgical, medical, obstetrical or dental operation, examination, act or procedure, or during childbirth, shall be liable on conviction before a court of summary jurisdiction for such offence to a penalty not exceeding £10, and in the case of a second or subsequent conviction to a penalty not exceeding £20; provided always that a person shall not be liable to a penalty under this section if in conducting such administration he was acting under the immediate direction and supervision of a legally qualified medical practitioner, or if, having been registered under the Dentists Act, 1878, he conducted such administration for a dental operation, act, or procedure, with one or more of the drugs or substances specified in the schedule hereto affixed, or if the circumstances attending the administration were such that he had reasonable grounds for believing and did believe that the delay which would have arisen in obtaining the services of a legally qualified medical practitioner would have endangered life.

2. Any person other than a legally qualified medical practitioner registered under the Medical Acts who shall inject, insert, or otherwise introduce, or shall cause to be injected, inserted, or otherwise introduced into any part, cavity, organ, or tissue of any other person through any puncture, incision, or other breach of cutaneous, mucous, or other surface for that purpose made or produced, any drug, medicament, or substance, whether solid, liquid, vaporous, or gaseous, and whether pure or mixed with any other drug, medicament, or substance, with the object of producing a state of insensibility to pain without unconsciousness, during any surgical, medical, obstetrical, or dental operation, examination, act, or procedure, or during childbirth, shall be liable on conviction before a court of summary jurisdiction for such offence to a penalty not exceeding £10, and in the case of a second or subsequent conviction to a penalty not exceeding £20, provided always that a person shall not be liable to a penalty under this section if in attempting to produce or in producing such insensibility to pain without unconsciousness he was acting under the immediate direction and supervision of a legally qualified medical practitioner, or if, having been registered under the Dentists Act, 1878, he attempted to produce or did produce such insensibility to pain without unconsciousness for the performance of a dental operation, examination, act, or procedure, or if, acting under the immediate direction and supervision of a person registered under the Dentists Act, 1878, he attempted to produce, or did produce, such insensibility to pain without unconsciousness for the performance of a dental operation, examination, act, or procedure.

3. The expression "court of summary jurisdiction" in this Act shall have the same meaning as in Subsection 11 of Section 13 of the Interpretation Act, 1889. In Scotland it shall mean any justice of the

peace and also the sheriff. The expression "the Medical Acts" shall mean the Medical Act, 1858, and any Acts amending the same passed before the passing of this Act.

4. This Act may be cited as the "Anæsthetics Act."

No filled-up schedule was attached to the draft.

The Anæsthetics Committee recommended that the Council should communicate to the Lord President the following observations on the draft Bill:—

1. That, without committing itself to an opinion on mere points of drafting, the Council recognises that the Bill as submitted gives practical effect to the Council's conclusions on the subject, which have already been communicated to the Lord President.

2. That in Clause 1 it is desirable that a provision should be introduced making it clear that a person registered under the Dentists Act, 1878, is not prohibited from administering for a legally qualified medical practitioner one or more of the scheduled anæsthetics in connexion with an operation, act, or procedure other than dental conducted by such medical practitioner.

3. That in Clause 2 it is desirable that provision should be made for prohibiting the application or administration by unqualified persons of dangerous anæsthetic drugs to unbroken surfaces in connexion with dental or other operations, acts, or procedures; and that with this object the limiting words, "through any puncture, incision, or other breach of cutaneous, mucous, or other surface for that purpose made or produced," might with advantage be omitted.

4. That in Clauses 1 and 3 it may be desirable to provide explicitly for an appeal to a court of quarter sessions or other corresponding court against a conviction made under the Act by a court of summary jurisdiction.

5. That, in the opinion of the Council, it is of importance that, for the protection of the public against the dangers disclosed in the Report of the Departmental Committee appointed by the Secretary of State, legislation on the lines of the Bill submitted should speedily receive the sanction of Parliament.

6. That, in case it is decided to bring such a Bill before Parliament, the Council would be prepared to suggest the terms of the necessary schedule, including therein in the first instance *nitrous oxide gas*.

Sir HENRY MORRIS formally moved that the report should be adopted.

Dr. KNOX seconded.

Sir THOMAS FRASER said that whilst he entirely sympathised with the purport of the Bill, he thought there was some ambiguity in the second clause. Did it entitle a nurse, who was under the direction of a medical man, to make an injection whilst she was not actually under his immediate supervision?

The PRESIDENT said that points of drafting hardly concerned the Council at this stage, because it had no assurance that the exact text now submitted would ever come before Parliament. The Bill would have to be submitted to draftsmen and to the law officers of the Crown. He had the assurance of the Government that when the Bill was redrafted it would come before the General Medical Council. Therefore it was better that members should reserve their criticisms on points of detail until that stage. This draft was a preliminary sketch and the Council had been asked whether it was on the right lines. He had no doubt that the point raised by Sir Thomas Fraser would have to be considered.

The motion was agreed to.

Instruction in Professional Ethics.

Dr. LATIMER moved:—

That the Council should recommend to the several licensing bodies the addition to the latter part of the curriculum of some instruction in professional ethics, and that this recommendation should also apply to the dental curriculum.

He said that owing to the cessation of the old method of admission into the medical profession by way of pupilage to a medical practitioner one opportunity was lost to the medical student to come under the instruction and guidance of an elderly and experienced practitioner. Eloquent testimony had been borne at various times to the efficacy of this practice in regard to professional ethics. He had often heard the view expressed in medical circles that it would be a great advantage to the medical student that he should have some instruction in ethics. Many cases which came before the Council and also many cases which individual members came across in the large towns convinced him that there were medical men who departed from the code of medical ethics, because they were uninstructed in it. He did not propose that anything should be done more than to request the licensing bodies that a student should have one or two lectures delivered to him on the subject. The greatest advantage would accrue to young men if before leaving college they learned the pitfalls which they might meet with in their after career. There was an honourable professional code in the medical profession. He had seen it departed from. He had seen medical men fighting for an appointment as if they were engaged in a political battle. They canvassed workmen for their votes, and he believed that if the matter had been brought before the Council it would have taken a very severe view of the conduct. It was not an examination which he wished to institute in this matter: it was something in the nature of a kindly lecture. Medical students about to take their place in the ranks of the profession should learn the true relationship of principal and assistant and the relationship of medical man to patient. Guidance was also required in regard to such matters as advertising and the question of certification. Several members of the Council to whom he had spoken thought it desirable that the matter should be dealt with in a post-graduate course. He was not at all sure that that was the wisest plan. He hoped that the motion would be regarded as a suitable one.

Dr. LANGLEY BROWNE seconded. He considered that it would be extremely useful that the student should know before the end of his career the pitfalls which he should avoid and the courtesies which he should carry out when he went into practice.

Dr. NORMAN MOORE remarked that he was sure that all members of the Council sympathised with Dr. Latimer's aim that all students and practitioners in medicine should be guided by a proper code of morals. He differed from Dr. Latimer as to the means suggested—namely, of having a course of lectures in the medical schools. The authority of any course of lectures on the subject would depend upon the person who delivered them. That was a very important point. Let members of the Council look at medical etiquette and the conduct of practitioners from one end to the other. Was there anything more in the matter than that medical men should behave according to the ordinary precepts of morals and as gentlemen? He did not think there was more in it than that. It was desirable in the highest degree that all teachers of medical students should by their example do all that they could to encourage in the students rectitude of conduct. It would not be an advantage to have such lectures. The ordinary code of morals and the behaviour of a gentleman was what was required from a practitioner.

Sir CLIFFORD ALLBUTT considered that it was of high importance that these questions of conduct should be brought before medical students. It was very good for them to know how these principles could be applied.

Dr. SAUNDBY remarked that he had long held the opinions which had been expressed by Dr. Latimer. In the University of Birmingham some years ago he gave three or four lectures on the subject of professional ethics. These lectures were largely attended by practitioners, but the students did not come to them. They failed to reach the men whom he wanted to reach. After delivering these lectures for three years he stopped them, but afterwards published them in a book. If such lectures were to do good they must be made compulsory. If the student thought that it was a subject in which he was not to be examined he would neglect it.

Mr. TOMES said that the objection to Dr. Latimer's motion was that it would let the idea go out that there was a special system of ethics for the medical profession which was not applicable to other people. The principles of ethics might be laid down in lectures, but nobody had difficulty about the principles. The application of the principles could not be anticipated by lecture, and therefore the difficulties in practice could not be anticipated.

Dr. SAUNDBY observed that when he lectured on the subject he dealt with actual cases which had arisen, classifying them under different heads.

Sir CLIFFORD ALLBUTT pointed out that on admission to the Fellowships of the Colleges an imposing document concerning professional conduct was read out, and to its terms the candidate gave his pledge.

Dr. NORMAN WALKER said that he did not find students in Edinburgh quite so careless about these questions concerning professional conduct as they seemed to have been in Birmingham. He found that the views of the students in Edinburgh were often critical of the General Medical Council. They thought that the Council's rulings were extremely severe. The reason of this was that the reports of its proceedings in the ordinary newspapers conveyed an idea of severity which he did not think was justified. He did not see why the teacher of medical jurisprudence might not add one or two lectures on the subject of professional conduct to his students, who would be senior men.

Dr. MANN thought it advisable that teachers in their lectures should let students know that they would be very glad to give advice on this subject, and should encourage them to communicate with them, either personally or by letter. That was his practice.

Sir THOMAS MYLES thought that steps should be taken to advise young medical men of their responsibilities, but any attempt to teach a hard-and-fast system would be open to the objection that when an emergency arose outside the scope of their instruction they would not know how to apply the code.

Dr. LATIMER briefly replied to the discussion.

Sir D. C. MCVAIL thought that Dr. Latimer had done great service in bringing the subject forward, but suggested that he should rest satisfied with the line the discussion had taken and not press his motion to a division.

Dr. LATIMER: In response to that appeal I shall not press the motion.

The motion was by leave withdrawn.

Unqualified Practice Prevention Committee.

On the motion of Dr. LANGLEY BROWNE an interim report was received from the Unqualified Practice Prevention Committee. It was in the following terms:—

The report as to the practice of medicine and surgery by unqualified persons in the United Kingdom, presented to both Houses of Parliament by command of His Majesty, was received by the committee. It was resolved that the report should be fully considered at a future meeting of the committee, and that the committee should report thereon to the next meeting of Council.

The Medical Curriculum and the Preliminary Examination.

Dr. MACKAY presented a report from the Education Committee upon a resolution remitted to it by the Council regarding the curriculum and upon the preliminary examination in general education. The resolution, which was passed on Nov. 26th, 1909, was in the following terms:—

That it be referred to the Education Committee to consider further the place in the student's career which the preliminary sciences should occupy; and that the committee be requested to frame and submit to the Council a pattern scheme of medical education whereby the required minimum of the several subjects to be included in the curriculum can be adequately studied and the requisite examinations thereon passed within the period prescribed by the curriculum.

Dr. Mackay said, in explaining the terms of the report which the committee had brought up on this resolution, that only in regard to the preliminary examination did the committee bring forward a recommendation which would require the sanction of the Council to be made effective. In regard to the question of the preliminary sciences, the Education Committee after an analysis of statistics had come to the conclusion that the energies of the great majority of the schools of the country ought for some time to be entirely absorbed in raising the standard of the general education of their pupils to the position which it ought to occupy. As was shown by the report, the committee had been enabled to furnish the Council with statistics as to the number of the candidates who had sat the first professional examination of the Conjoint Board of England on the strength of a school curriculum alone. The secondary schools which the Board recognised numbered 49 in all, and, as they had been specially inspected with a view to ascertaining that they were adequately equipped for the work, they might be regarded as specimens of the best of their class. The Conjoint Board had recognised instruction in the preliminary sciences in institutions other than universities and medical schools for a period of 16 or 17 years. A very small proportion of students had received instruction in this manner. The committee had been forced to the conclusion that as this very small proportion came from the best schools in the country it was practically impossible to expect that the ordinary secondary schools could at the present time take up the work. The figures which had been received by the committee showed that only a very few, and these apparently of exceptional ability, coming from the best schools in the country, were prepared to undertake the first professional examination upon a course of school study; and they confirmed the view of the committee that the schools of the country generally were not at the present time in a position to take up the work. The committee were of opinion that the question contained in the proposal to delegate indiscriminately to the school curriculum the subjects of the first professional examination was one which was not ripe for the consideration of the Council. It might be said that the Council ought to recognise the schools which the Conjoint Board had already recognised. If the Council would but enter into this matter a very long and difficult discussion would be the result. If it began the recognition of schools, the incline was so steep that the claims of all secondary schools putting forward candidates could not be resisted, and the result would be that the standard of examination in the preliminary sciences would be lowered beyond any possibility of retrieval. The second point referred to the committee was the suggestion that a pattern curriculum should be established. The committee came to the conclusion that it could not draw up a curriculum under which the required minimum of the several subjects to be included could be adequately studied, and the required examinations thereon passed by the average student within the period prescribed by the curriculum. The period of five years was to be regarded as the minimum of time to be allotted to the course of study, and it was not unnatural that only the best or the most favourably situated of the candidates found it sufficient. He would point out that it would be a very difficult matter for the Education Committee to draw up a pattern curriculum. Let the members of the Council look over the curricula of the different licensing bodies. They would not find one amongst them which was not a satisfactory curriculum. They differed from each other in different ways. If the Council were to determine upon a pattern curriculum, that curriculum must be a minimum one. He did not think there was a single existing curriculum that could be called a minimum curriculum. One was perhaps comparatively weak in one point, but strong in another. If a pattern curriculum was established, it must be a mimimum curriculum in each individual subject. In his opinion it would be a retrograde step if one were to be drawn up. The third subject which had been under the consideration of the committee was the preliminary examination in general education. He quoted at length from the report of the committee on the considerations which had weighed with it and the conclusions which it had reached. He referred to the improvement of education conditions in England and Scotland. The committee had come to the conclusion in regard to the examinations now recognised as preliminary examinations for medical study, that the elimination of those examinations which are most distinctly "junior" in type would not have the effect of diminishing to any considerable extent the number of the candidates entering the profession or of compelling examiners to a laxity in marking which would tend to lower the level of the higher examinations. On the other hand, the evidence seemed to point to the conclusion that the removal of these examinations from the preliminary list, if sufficient time were given to allow the change to be accomplished gradually, would be fully met by the improvement in the educational conditions of the country which was now taking place and was sure to extend. The change would certainly be welcomed by the schools as an educational advantage, as it would tend to prevent the premature withdrawal of the bright youth from his school career at an age when the crowning part of the work remained to be done. The committee brought forward a recommendation to give effect to their views. It was not proposed that it should apply to dentists. In conclusion Dr. Mackay moved the adoption by the Council of the recommendation of the committee, which was in the following terms:—

That on and after the close of the year 1913 the following examinations be removed from the list of the preliminary examinations recognised by the Council as qualifying for entrance on the curriculum in medicine: The Junior Local Examination of the University of Oxford; the Junior Local Examination of the University of Cambridge; the College of Preceptors Preliminary Examination for Medical Students; the Educational Institute of Scotland Preliminary Examination; the Royal College of Physicians and Surgeons of Ireland Preliminary Examination; the Intermediate Education Board of Ireland Middle Grade Examination.

Dr. NORMAN MOORE seconded.

Sir HENRY MORRIS said that in regard to the preliminary sciences and the pattern curriculum the report left things as they were. The reply of the committee was that it could not do as it was asked, and the only reason given for its inability to do so was the very remarkable one that only exceptional candidates could accomplish, within the allotted time, the study of the full number and amount of the subjects contained within the present curriculum. It was with the object that the committee should consider and report to the Council how this very condition of over-congestion of the curriculum might be obviated that the resolution of Nov. 26th,

1909, was referred to it. There were two ways in which the congested curriculum could be relieved—namely, (1) either by lightening the curriculum, or (2) by extending the period. The report did not deal with either alternative. It left things exactly as they were. It had made no attempt whatever to adapt the quantity of the contents to the containing space, and the only reason given for its not doing so was that the contents were greater than the space could contain. The committee was not asked to draw up a pattern curriculum which would prove acceptable to the majority of the licensing bodies and which would remove the diversity of detail among the curricula. It was not asked even to draw up a pattern curriculum. What it was asked to do was to draw up a pattern curriculum whereby the required minimum of the subjects included could be adequately and successfully studied within the period prescribed by the curriculum by the average student. The members of the Council knew how improbable it was that any pattern scheme would be accepted by all the licensing bodies, or that diversity of detail among the curricula could be prevented. Diversity of detail in a possible curriculum would be no bad thing. What was the mischief was, that the present curriculum was impossible to the average student. That was the darkness into which the Council asked the committee to throw the light. But the result of its report was that the students and their parents were left uninformed by the Council of the fact that a nominal five years' curriculum must in reality be one of six and a half or seven years; and the parent who launched his son as a medical student and expected to see him through on the expenditure of from £800 to £1000, had, by bitter experience, to realise that it was only after an additional year and a half or two years of time, and an additional £200 or £400 in cash, that the qualification which he and his son had in view could be attained.

The first part of the resolution of Nov. 26th, 1909, was "that it be referred to the Education Committee to consider the place in the student's career which the preliminary sciences should occupy." The reference was not as to the place in the curriculum, but as to the period of the student's career, which the preliminary sciences should occupy—as to whether they should be studied within the period of the curriculum, or previously. The answer of the committee might have been simple and direct, to the effect that the precise period should remain, as in fact it was now, optional; but that if previous to registering, but after passing an examination in general education, the curriculum should be correspondingly shortened by 6 or 12 months. Or its reply might have been that the period should be before the commencement of the curriculum, and that the curriculum, unburdened of the preliminary sciences, should remain at five years. The reply of the committee implied an untruth—of course, quite unintentionally, but still an untruth—that the preliminary sciences must be studied in the five years and in medical schools or in scientific institutions. The wish was father to the thought, and the thought to the implication. The reasons given for this reply are two: (1) that to transfer the subjects from the curriculum, and make them part of the course of school education, would be to remove them from any effective control on the part of the medical authorities; and (2) that the indiscriminate delegation of these subjects to the school curriculum was a matter which was not ripe for the consideration of the Council. The answer to the first was, that if the preliminary science subjects were made part of the school course, the examination in them would be under the same kind and extent of influence as the subjects and standard of the examination in general education. The answer to the second was given by Huxley in 1889. as well as by the teachers, and by the writers of an important document 20 years ago. Now these subjects, as long as they are retained in the curriculum, either ought to be exclusively studied in a medical school and taught by teachers in touch with the whole course of medical education, or their study elsewhere than at a medical school under specified conditions ought to be recognised. The question might be set aside of their being taught by men in general touch with the medical curriculum as a whole, because whether taught in a medical school or not they were taught by teachers who regarded the study of these subjects as the first steps in a science education, and who very little considered their special bearing on other parts of the medical curriculum; whereas the study of organic chemistry in its bearing on physiology and pathology was provided for within the limits of the professional curriculum. But if the study of these subjects was not to be of necessity within a medical school, then on what code of justice was the study of them in a highly equipped secondary school to be prohibited? Why are schools like Epsom, Dulwich, Bedford, St. Paul's, University College School Frognal Hampstead, to be prohibited, whilst polytechnic institutions and municipal technical schools, and several others mentioned on p. 13 of the Students' Regulations of the General Medical Council are recognised?

The report gave two statistical tables and stated that these tables showed that only a very few boys, and those apparently of exceptional ability, were prepared to undertake the first professional examination upon a school study. This was an incorrect and a misleading assumption for three reasons. In the first place, amongst the boys who pass the preliminary scientific (first professional examination) of the University of London as external students are a considerable number from secondary schools, many of whom come for examination in the advanced subjects to the Conjoint Board, and thus are not returned in the tables as coming from secondary schools, though it had been from secondary schools that they presented themselves for examination at the University of London. In the second place, at least half of the Conjoint Board candidates are University graduates or undergraduates, and are therefore exempt from examination in the preliminary sciences at the Conjoint Board. In the third place, there are many who had done a part of their preliminary science studies at secondary schools and the rest in a medical school and are tabulated as having come from the latter. But in so far as the number of candidates from secondary schools, with highly equipped modern sides—with excellent laboratories and highly qualified teachers—were fewer than might be expected, one cause was the misleading and inaccurate, "so-called," regulation No. 12 on p. 14 of the Council's publication, "Registration of Medical Students," and which the Report left without reference, untouched and uncorrected. This regulation was not only misleading and inaccurate—it was directly contrary to the facts. By that clause the Council was made to appear as usurping a power which belonged to the licensing bodies alone, and sometimes the Council was put into a very ridiculous position thereby. The General Medical Council could not refuse to place a man on the Register if he had passed his examination in general education and in preliminary science from school and graduated M.B. Lond. four years after registration. As long as Regulation 12 remained amongst the regulations of the Council an injustice was done to the boys, to the parents and to the secondary schools. In conclusion, he said that he was prepared to move the following motion:—

That as the Education Committee in their report of Nov. 22nd, 1910, express views in favour of retaining the preliminary sciences (chemistry, physics, and biology) as subjects of the medical curriculum, it be referred to the committee to consider and report to the Council as to the best way of amending the regulations of the General Medical Council in regard to the registration of medical students with the objects (1) of making those regulations consistent with the report and with the powers of the Council; (2) of making clear the distinction between regulations which must be observed and recommendations made for the students' guidance; and (3) of the advisability of altering or deleting Regulation 12 on page 14 of the regulations printed under date June 1st, 1910.

The PRESIDENT said that the motion of Sir Henry Morris really related to a different subject than that raised by Dr. Mackay's motion, which concerned the preliminary examination alone. Sir Henry Morris might, however, bring it forward as bearing on the first and second parts of the report after Dr. Mackay's motion, which dealt only with the third part, was disposed of.

Mr. THOMSON remarked that the Council might take some further expert advice on the value of these junior examinations.

Sir CHARLES BALL moved as an addition to Dr. Mackay's motion:—

That the Education Committee be authorised, on behalf of the Council, to communicate with the Commissioners of Intermediate Education in Ireland as to the possibility of establishing a satisfactory preliminary examination in education under the control of the Commissioners suitable for students commencing the study of medicine.

Such a substitute, he said, was absolutely necessary in Ireland. There was nothing in Ireland comparable to the leaving certificate. This addition was agreed to.

Sir C. NIXON seconded.

Dr. MACKAY accepted the amendment.

Dr. MACKAY's motion as extended by Sir Charles Ball's amendment was agreed to.

Sir HENRY MORRIS then formally moved the motion, the terms of which he intimated at the conclusion of his speech.

Dr. LANGLEY BROWN seconded.

It was unanimously agreed to defer further consideration on the motion until the next session of the Council in May, 1911.

Instruction in Scientific Subjects.

On the motion of Dr. MACKAY a report in the following terms was received from the Education Committee:—

On May 28th, 1910, the Council received a memorial relating to the position of the purely scientific subjects of chemistry, physics, botany, and zoology in the medical curriculum, which, on the motion of Dr. Saundby, was referred to the Education Committee for its consideration.

The subject to which the memorial refers having been dealt with specially in the report of the committee, further comment appears to be unnecessary at the present time. The committee would thank the memorialists for the expression of their views.

Instruction in Ophthalmology and Otology.

Dr. MACKAY presented a report from the Education Committee. It set out that—

On May 28th, 1910, the following resolution by the Examination Committee was referred to the Education Committee for its consideration:—

In the curriculum of all the licensing bodies, with three exceptions, special courses on ophthalmology form an essential part. The committee are of opinion that every student of medicine should receive some special instruction in the subject. The committee do not think it necessary to insist that every student should be examined in ophthalmology, but they are of opinion that all students should be liable to be examined in some branch of the subject.

While the committee would commend the practice of giving specialised instruction in otology and diseases of the throat they do not think it necessary to insist, in the present crowded condition of the curriculum, that special courses and examinations should be made obligatory, provided the subject be included under the general headings of Medicine and Surgery.

The report was received.

Conclusion of Session.

A vote of thanks having been awarded to the chairman for his services in the chair, the business before the Council for the winter session was concluded.

The Council rose and will meet again in May, 1911.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Rearrangement of Coroners' Districts.

THE Public Control Committee in a report to the London County Council on Nov. 22nd referred to the resolution passed by the Council on Oct. 11th praying the King to order such alterations in the boundaries of the coroners' districts, exclusive of the franchise districts, as to make them coincide with the boundaries of the metropolitan boroughs. One effect of such an adjustment would be that extensive alterations would be made in the areas comprised in the southern and south-western coroners' districts, and since the Council's decision the committee had been advised that serious difficulties in regard to compensation, &c., might be encountered in taking steps to carry out the alteration of boundaries in the two districts mentioned. The committee was of opinion, therefore, that the alterations of boundaries should be confined at present to those cases in which the boundaries did not coincide because of alterations of parish areas. At the meeting on Nov. 22nd and again on Nov. 29th the consideration of the report was adjourned.

Observance of Health By-laws.

Replying to a question as to the enforcement of the Council's by-laws as to spitting on tramcars, Mr. White, chairman of the Highways Committee, said that seven convictions for contravention had been obtained and a few hundred letters of caution had been sent. It was extremely difficult for the conductors to deal with the matter, and he wished passengers could be persuaded to help. It would then be possible to do a great deal to check this objectionable habit.

Administration of the Provision of Meals Act.

The Education Committee of the Council on Nov. 23rd received from the Children's Care Subcommittee an exhaustive report on the working of the Council's scheme for providing meals for necessitous children. The subcommittee stated that existing arrangements by which children attended at either (*a*) buildings hired by or lent to the Council, (*b*) coffee houses, and (*c*) private dining centres were not completely satisfactory. It was difficult to ensure a proper supply of meals. As an alternative—notwithstanding the Board of Education's objection—the subcommittee thought it would be better to make a wider use of school halls. Teachers and others had urged numerous objections to this course, but the subcommittee stated that the children could all leave by 1 o'clock, so that there would be ample time for ventilation; the spilling of food was a trivial matter—all that was necessary was that the helpers should pick up anything on the floor of a greasy nature and the halls should be washed fortnightly instead of once in three weeks. The provision of accommodation for washing up was a difficulty, but it could be met by building annexes. The whole number required would cost £20,000. The subcommittee had to admit that from the Council's point of view the decision to enter into a four years' contract with an outside body for the supply of meals was ill advised and added that the ideal method would be the establishment of a dining hall and kitchen for each group of schools. The discussion was adjourned. On Nov. 30th, after debate on points of detail, the proposals of the subcommittee were agreed to.

Cleansing of Verminous Children.

The subcommittee also reported as to the cleansing of children infested with vermin, recommending that as the number of such children would probably show a progressive diminution arrangements should be made to use borough council cleansing stations rather than go to the expense of establishing special stations at the schools. Thirteen borough councils—the City Corporation made a free offer—were willing to do the work at a charge of 2*s.* per head, and agreements for one year should be entered into. For the remaining districts the County Council would have to make its own arrangements, adapting existing buildings or putting up temporary ones. Any scheme for cleansing the bodies and clothing of children would be ineffective unless their homes were cleansed too, and the borough medical officers were willing to coöperate in this. It was estimated that about 20,000 children required cleansing, and the agreements with the borough councils would provide for 12,000 of them. Three visits to the cleansing station would be necessary in each case. The proposals were agreed to.

Cost of Dental Treatment.

The subcommittee submitted a fresh recommendation in regard to the recovery from parents of the cost of dental treatment,[1] advising that instead of the definite charges then proposed each case should be considered on its merits, provided that some charge was made in all cases and that in no instance should the amount paid by the parent exceed 1*s.* As in the case of medical treatment, legal proceedings would not be taken where the local care committee was of opinion that the parents could not pay. The recommendation was approved.

Medical Treatment at Hospitals.

At the meeting of the County Council on Nov. 29th Mr E. A. H. Jay, who has just succeeded Mr. Cyril Jackson as chairman of the Education Committee, and who took a prominent part in the organisation of medical treatment in London through the agency of the hospitals, had charge of the Education Committee's report. He stated, in reply to a question, that inquiry had been made into the allegation, voiced by several speakers during recent debates on the question of medical treatment, that children had been sent away from certain hospitals because they had not with them a card issued to each child attending under the Council's scheme of medical treatment. The secretary of the St. George's Hospital wrote that every patient who applied for medical relief was treated, no distinction being made between patients coming with or without letters, or between attending school and voluntary patients. The authorities of the Poplar Hospital and of the East London Hospital wrote in similar terms.

[1] THE LANCET, Nov. 19th, p. 1507.

THE LANCET.

LONDON: SATURDAY, DECEMBER 3, 1910.

The Report of the Chief Medical Officer to the Board of Education.

THE annual report for 1909 of the chief medical officer to the Board of Education, presented to Parliament on Wednesday last, is a document of great interest and extremely cheerful tendency. Dr. GEORGE NEWMAN, chief medical officer to the Board, explains that the report is somewhat fragmentary in form and substance, adding that it is "a plain record and must speak for itself," and this it does in unmistakable terms, the account of the work done being given in so clear and comprehensible a manner that the lessons conveyed cannot escape the reader. Nor can the net message of the report be overlooked, which is that a vast revolution is taking place in our physical care of the youth of this country, the most active agent in which is systematic medical inspection of the State-educated children. Facts have been collected with regard to the administration of medical inspection and treatment, the physical education of school children, and the provisions made for defective or feeble-minded subjects, most of which are quite new, and some of which raise questions of far-reaching social importance. These things speak to work accomplished, and from reading the account of them we arrive at two conclusions, both of which are in accord with the expressed views of the chief medical officer. The first is, that in spite of all difficulties, limitations, and adverse conditions the national system of medical inspection and supervision of school children has now been established throughout England and Wales on a working basis; and the second is that the work of this system has not resulted, as was so freely prophesied would be the case, in the mere collection of statistics, but has, on the contrary, brought about a new social condition among us, under which thousands of children are now receiving physical aid, and in a secondary manner moral support, the absence of which has hitherto implied not only great misery to themselves but incalculable loss to the State.

During the year 1909 medical inspection became for practical purposes an integral part of the public health administration of the country. The fundamental principle of the Act of 1907, the Education (Administrative Provisions) Act, under which medical inspection became a statutory duty of local education authorities, was to promote the physical and mental development of children during school life, and the steps that were taken to this end have proved to be well-directed. The Act laid down that it was the duty of each local educational authority to provide for the medical inspection of children at admission to a public elementary school, while a later code made it a further requisition that all children should be examined upon leaving. Sooner or later there will be a third inspection age-group intermediate to these, and local education authorities may already expect to undertake this responsibility. As the schedule of medical inspection laid down by the Board of Education has been almost universally adopted by the authorities, some even stiffening it by actually requiring more information concerning their young charges than the schedule of the Board demands, we seem to be within a reasonable distance of the time when all our children will obtain the benefits of the new legislation in a thorough manner. London, where undoubtedly the situation is more acutely hard than anywhere else in the country, lags behind. The complicated difficulties under which the London County Council finds itself are well known to everybody, and for the present the Council school children of the metropolis will be placed at a disadvantage, but there is a sincere wish on the part of the Council to meet the situation squarely, and this being the case, we must hope that progress will soon ensue. The scheme of medical inspection is now approved and school medical officers have been recognised by 314 out of 327 local education areas. In these 314 cases the medical officer of health has been selected as school medical officer in 230 cases, while in the remaining 84 cases 74 school medical officers have been appointed definitely under, or in connexion with, the medical officer of health, and the remaining 10 cases show in their appointment some degree of coöperation. From the very beginning of the movement which led up to the passing of the Act we were of opinion that inasmuch as school hygiene could never be divorced from home hygiene, the more sympathy, and even combination, could be secured between the educational authority and the sanitary authority in the matter of medical inspection the better it would be for the children concerned. The view did not find universal favour, and some well-qualified thinkers upon education considered it a narrow one; but events have since justified the attitude which we took up, while the allegation that the routine work of the school doctor, working in coöperation with a sanitary authority, would be so monotonous and uninspiring that the service would be unpopular with the progressive medical man has broken down. Nowhere does it seem that the duties of the school doctor are being discharged in a perfunctory manner. It is, on the contrary, and as Dr. NEWMAN notes, gratifying to record that the reports from the school medical officers contain frequent references to matters lying without the routine of inspection, but which have been made the subject of inquiry during the year. Among such miscellaneous subjects, which have been reported upon in 1909, may be mentioned the employment of children out of school hours, many matters relative to the feeding of children, the medical examination of children attending swimming-baths, the influence of exercise upon heart strain, the problem of dust in school buildings, the relationship existing between various groups of diseases, the home conditions of consumptive children, and so on. The reports of school medical officers containing work upon these and other matters have many of them been reviewed in our columns upon their appearance, and we are able to testify to the interest created by such inquiries, while their value from a national point of view

may become very great. We therefore cordially endorse Dr. NEWMAN'S suggestion that school medical officers, wherever the time or opportunity allows, should select a subject for investigation and report, for they would in this way constitute themselves into a standing commission with a roving reference upon the health of the children of the country during the school age, and we cannot conceive the institution of any commission which would more conduce to the national health, happiness, and prosperity.

Systematic "following up" is required if a local education authority is to ascertain how far its system of inspection is not being wasted, and whether the facilities existing within its area, alike for prevention or for treatment, are being used. "Following up" is the stage intermediary between inspection and treatment. The result of the inspection having been communicated to the parent or guardian of the child, the next step is to make inquiries after a reasonable interval whether the remedy has been taken and why failure may have resulted in certain cases. In these proceedings the part played by the parent is, in our opinion, of paramount importance, and however inconvenient it may be sometimes, when the saving of time and perhaps the saving of space is an object, to dispense with the presence of the parents at the inspection of their children, there can be no doubt that parents ought to be urged to be present whenever possible If they have seen the inspection they can by word of mouth be impressed with the importance of the treatment recommended for the child, when they often become, to the surprise of their neighbours, pioneers of sanitary progress in their district. The influence of the teacher is also extremely weighty. Indeed, in the last annual report of Dr. THRESH, the county medical officer of Essex, the statement occurs that the head teacher is the dominating factor in the situation. This depends upon the personality of the head teacher and the measure of his hygienic knowledge; where, as is the frequent case, the head teacher is in full coöperation with the school doctor, the influence for good is without bounds, but an unprogressive attitude on his part is proportionately unfortunate. The school nurse and the school attendance officer have also their part in the work of following up, but the duties of the school nurse in assisting at the routine of medical inspection are very valuable, and it has to be remembered that if she is detached from these duties to do house-to-house visiting among the parents of the children she will not be so available for her other functions. It has been suggested that where this is the case the services of the district nurse, where there is one, should be employed, but the value of these services is not so great. Lastly, there remain care committees, and of the work of these excellent agencies we say but little now. Care committees are as yet formed on no particular pattern, and being frequently branches of existing organisations have varying precedents upon which to work. Dr. NEWMAN writes with full appreciation of the generous services of these voluntary bodies, whose use, we are sure, will be greater when a definiteness of aim has led to more uniformity in their work.

Dr. NEWMAN makes the general statement that in respect of the six million children in the public elementary schools of England and Wales about 10 per cent. of them suffer from serious defects of vision; from 3 to 5 per cent. suffer from defective hearing; 1 to 3 per cent. have suppurating ears; 8 per cent. have adenoids or enlarged tonsils of sufficient degree to obstruct the nose or throat and to require surgical treatment; 20 to 40 per cent. suffer from extensive and injurious decay of the teeth; 40 per cent. have unclean heads; about 1 per cent. suffer from ringworm; 1 per cent. are affected with tuberculosis of readily recognisable form; and ½ to 2 per cent. are afflicted with heart disease. The field for treatment is thus enormous. The immediate problems of the school medical service are to ascertain in each area what children are suffering from various defects and ailments and what is the character and degree of these ailments. In how many of these cases can the local education authority reasonably expect that, with the assistance of existing voluntary agencies, amelioration will be secured without further intervention by the authority? This has to be considered. Dr. NEWMAN'S report deals as fully as possible with the action taken by various local education authorities in respect to medical treatment, but the problems here involved have only been seriously considered by any large quantity of education authorities for a little over a year, and no very complete or symmetrical tale can be expected. During the year 1909 Dr. NEWMAN is able to report a widespread improvement of school arrangements, showing that the lighting, heating, ventilation, and sanitary condition of school buildings generally have received a degree of attention hitherto unknown. Much of this improvement of the sanitary environment of both teacher and taught has been due to the inspections and recommendations of school medical officers. The machinery of actual treatment has been set in work in numerous directions. Some authorities have arranged that the nurses employed to assist in inspection should be employed in the duties of treatment, acting in conjunction with the general practitioners, upon whom the care of many of these children devolves. Other authorities have made contributions out of the education rate to existing nursing associations in return for services in the care of the State educated children. Some authorities have decided to provide suitable and inexpensive spectacles free of charge after due precaution that the children's eyes have been examined by medical men and that the parents were unable to provide the spectacles for their offspring. Twenty authorities have made contributions out of the education rate to hospitals, and under these arrangements a large number of children have received treatment during the year; and despite the fact that this proceeding must be regarded critically, it certainly seems to have the advantage of simplicity. What is required, however, is a safeguard against resort to the hospitals by children whose parents are well able to pay for medical attendance elsehow. Such are the directions which treatment has so far followed; those who know little of the difficulties involved may not be impressed by what has been done, but those who have followed the course of what is really a social revolution will take a different view. They will join with us in congratulating Dr. NEWMAN upon being in a position to tell a story of such sound performance and such magnificent promise.

The Danger of the Enteric Fever Carrier.

THE existence of the "carrier state," and the infective ability of the "carrier," are conditions which are now almost universally recognised as important in the causation of enteric fever. In this country the inquiries of medical officers of health, medical inspectors of the Local Government Board, and army medical officers have brought to light several striking examples of the spread of infection by individual carriers. The subject has been studied abroad, in France and America, and on a larger scale in Germany at the bacteriological stations established in connexion with the elaborate campaigns against enteric fever which were organised some six years ago in Bavaria and Alsace-Lorraine. Valuable contributions have also been made in India, from the Central Research Institute at Kasauli, in Japan, and in other countries. The literature, however, is widely scattered and much of it difficult to obtain, so that hitherto it has hardly been possible for the English reader to obtain a comprehensive statement of the present state of knowledge on the prevalence of carriers and the bacterial conditions associated with them. The difficulty has been removed by the publication of a special report on "The Enteric Fever Carrier," which has been made to the Local Government Board.[1] In order that the information available from home and foreign sources might be systematically abstracted and reviewed from a bacteriological standpoint, the work was entrusted to Dr. J. C. G. LEDINGHAM, who is to be congratulated on the success with which he has carried out a very laborious task. The volume supplies information and commentary on all the principal instances of infectivity of carriers, the pathogenesis of the carrier state, and the treatment of carriers. Its issue will naturally lead to new inquiries regarding the degree of importance to be attached to the operations of carriers in explaining the spread or maintenance of enteric fever in this country. One such inquiry has already been made by Dr. THEODORE THOMSON, who collaborated with Dr. LEDINGHAM in the Local Government Board investigation, and has contributed a comprehensive and well-balanced review of the epidemiological considerations involved in his presidential address to the Epidemiological Section of the Royal Society of Medicine on Nov. 14th last. The enormous capacity for mischief of certain carriers to the people with whom they live or to the inmates of institutions for which they work has been proved beyond doubt. In the Göttingen case, reported by ROSENTHAL, a woman appears to have been responsible for the infection of at least 13 people for whom she prepared food between 1897 and 1906; the New York cook, according to SOPER'S inquiries, may be considered responsible for the occurrence of no fewer than 26 cases of typhoid fever in seven different families; the Brentry carrier, studied by DAVIES and WALKER HALL, is held to have originated enteric fever outbreaks in at least three institutions between 1904 and 1908; and several equally striking examples of intense and prolonged infectivity are given in this report. Carrier cases have also been suspected on many occasions of originating outbreaks or maintaining endemic typhoid fever in particular localities. Their ability to do so is supported by very strong circumstantial evidence, implicating healthy persons ascertained to excrete the bacillus typhosus, and rendering it unnecessary to assume strings of undiscovered or "missed" cases of enteric fever, for the existence of which no evidence at all can be found. Recent instances of the kind have been reported in England by Dr. R. W. JOHNSTONE and other observers, and accord with the results of many foreign investigators.

The carrier is a person, usually a woman, who, although in good health, carries the infectious material in the body and excretes the bacillus typhosus in fæces or urine. The excretion of the bacillus may continue, persistently or at intervals, during many months or years. The carrier state is not necessarily the result of a previous attack of enteric fever, or at least of any illness which can be traced or is known to the carrier. Enteric fever patients, however, may continue after convalescence to excrete the bacillus, sometimes for a period less than three months ("temporary carriers") and sometimes for much longer periods ("chronic carriers"), and it is naturally among persons who have been attacked by enteric fever that most carriers have been detected. Readers of Dr. LEDINGHAM'S report cannot fail to be struck by the magnitude of the observations which have been made by different bacteriologists with the object of ascertaining the existence of carriers and determining the frequency with which their excreta are infective. It is to be expected that these observers, working under different circumstances and employing different methods, would obtain very different statistical results, and that, other things being equal, a larger proportion of carriers will be found by those who have had the most frequent opportunities of examining excreta from individual cases. This is, in fact, the case, and much caution is necessary in accepting statistics representing either the proportion of carriers among those who have been attacked by enteric fever or the proportion of carriers present in a general population. But it would be wrong on this account to ignore the general trend of the evidence on these points. Taking strictly moderate estimates, it would seem that on the present criteria of the bacteriologist some 3 per cent. of enteric fever cases become chronic carriers. And as regards the proportion of chronic carriers in a general mixed population, a considerable series of observations is available which suggests the prevalence of carriers to an extent of something like 3 per 1000—a result which is perhaps surprising, but which we have no reason to consider in excess of the truth. The number of normal people, whether or not they have previously been attacked by the disease, in whose excreta the bacteriologists have found the typhoid bacillus is indeed relatively so high that current conceptions of the danger of the individual carrier must be very largely modified. On a basis of three persons liable to excrete typhoid bacilli per 1000 of the population, London alone would contain more than 14,000 carriers. And when it is considered that the total number of known enteric fever

[1] Reports to the Local Government Board on Public Health and Medical Subjects. (New Series, No. 43.) London: Wyman and Sons. Price 1s.

cases in London in 1908 was only 1357, and that carriers, however numerous, have not prevented the conspicuous decline which has taken place in the prevalence of enteric fever during the last half century, the danger of the average carrier would appear for practical purposes to be negligible. Carriers should be most abundant in towns which have recently passed through severe epidemics of enteric fever due, for example, to sudden water infection. Dr. THOMSON points out, however, that the prevalence of enteric fever in the years following the great water epidemics of Worthing in 1893, Maidstone in 1897, and Lincoln in 1905, was no greater than in the years preceding the water infection.

The infective potency of the average carrier, even when he is occupied in the preparation or handling of food, seems thus to be of a very different order to that of the Brentry dairywoman or the New York cook. Future inquiries may be expected to throw more light than we at present possess on the circumstances in which carrier infectivity becomes specially accentuated. Several observations noted by Dr. LEDINGHAM point to the importance of concurrent physiological or pathological conditions in the carrier which may lead to the periodical excretion of bacilli in unusual abundance or even in a state of increased virulence. And to a large extent, no doubt, the explanation is to be sought in other and less recondite circumstances. The dose of infective material is of consequence, and individuals of ordinary personal cleanliness should usually have few opportunities of conveying to others a harmful quantity of infective material derived from their fæces or urine. Again, many carriers are not concerned with food preparation and live in places where their excreta cannot easily contaminate soil or water. Dr. LEDINGHAM'S report contains a valuable account of the methods adopted with greater or less success in the medical treatment of carriers and of the precautionary or preventive measures which have been adopted when carriers have been detected. While strict surveillance seems necessary in the case of carriers of proved infective ability, especially where food preparation is concerned, there seems to be no warrant in our present knowledge for any drastic action in the case of every individual who has been ascertained by the bacteriologist to be in the carrier state. Fortunately, the principal measures which have resulted in the diminution of enteric fever in this country must have been as effective against the spread of infection by the carrier as against that of infection by persons suffering from the disease.

Practice by "Unqualified Persons."[1]

THE General Medical Council, in view of the evils to the community consequent upon the unchecked practice of medicine and surgery by unqualified persons, and after the completion of an inquiry which showed that in many countries the laws intended to prevent such practice are more stringent and more effective than those of the United Kingdom, intimated to the LORD PRESIDENT of the Privy Council, of which the General Medical Council is a department, that the Medical Acts do not sufficiently fulfil their declared purpose of enabling persons requiring medical aid to distinguish qualified from unqualified practitioners, and also that it is contrary to the interest of the public that medical and surgical practice should be carried on with impunity by persons holding no recognised qualifications. As a corollary to these propositions, the General Medical Council requested the Government to take steps for the appointment of a Royal Commission to inquire into the evil effects produced by the unrestricted practice of medicine and surgery by the unqualified persons referred to. On receipt of this communication the LORD PRESIDENT deemed it expedient in the first instance to have recourse to "ordinary means of information," and he appealed to the Local Government Board, the Scottish Office, and the Irish Government, asking that circulars might be addressed to the medical officers of health of each country inviting their opinion as to whether the practice of medicine and surgery by unqualified persons is increasing, and as to its effect upon the public health. The result, like the result of half measures in general, cannot be described as entirely satisfactory; but it has at least served to bring together a considerable amount of information and many opinions based upon extensive observation and experience. Replies to the inquiries have been furnished by over 1600 officers, and these replies have been summarised, either in the Privy Council Office or in that of the Local Government Board, for each division of the kingdom, although the Local Government Board expressly disclaims any responsibility for the views which are expressed. In each division the summary deals with quacks in classes, as herbalists, bone-setters, dentists, oculists, and so on, through the somewhat wide range of their various pretensions; and in each class we have a distinction between the mischief done by positively injurious treatment and the mischief done by treatment which in itself might be harmless, but which has prevented a proper course from being pursued in time. Under both heads the indictment is a terribly serious one, and reflects in the gravest manner upon a country by which such evils are tolerated.

A prominent place in the replies from all three divisions of the kingdom is given to the evils arising from the practice of midwifery by unqualified persons; but it is only in England that attention is specially directed to the proceedings of abortionists, whose practice is said to be "increasing considerably in many parts of the country," and where "advertisements of abortifacients appear in newspapers to an increasing extent." Specimens of the advertisements are given, and are of an exceedingly flagrant character, insomuch that no newspaper accepting them could plead uncertainty as to their true meaning and tendency. It will be remembered that we ourselves called attention to this subject 12 years ago in a series of articles entitled, "Quacks and Abortion," in which it became our duty to show that some of the newspapers professing the noblest sentiments were the most systematic offenders in this respect. We had the satisfaction of stopping the insertion of such advertisements for a time, but the exposure was forgotten, the smaller papers were again tempted, larger ones gradually

[1] Report as to the Practice of Medicine and Surgery by Unqualified Persons in the United Kingdom.

followed their example, and although the evil has not regained its original dimensions, invitations to produce abortion are again prominent in the columns of many of our popular instructors. The time has certainly come at which the admission of such advertisements should be rendered a criminal offence. Next to the abortionists, perhaps the chief stress is laid upon the doings of "bone-setters." We are told, for example, that their violent manipulations have occasioned real injury, that they undertake the cure of cancer cases with disastrous results, and that bad effects are reported from their treatment of cases of tuberculous bone disease, particularly in its incipient stages. It is manifest that in such cases they would often cause the dispersal of what might originally be a localised deposit, and that death from general tuberculosis might easily be an effect of their interference. A good deal is said of the treatment of eye disease by unqualified persons, especially by those assuming such titles as "ophthalmologist" or "qualified ophthalmic optician," or placing such letters as F.I.O., F.S.M.C. (Lond.) after their names, and thus leading the public to believe that they are fully qualified medical practitioners. The summary for England states that unqualified practice of this kind is strongly condemned in all quarters, and that eyesight has been seriously injured in many cases; while such conditions as glaucoma have not been recognised, and ophthalmia neonatorum has been treated with disastrous results. The unchecked diffusion of unrecognised infectious diseases, the cruel tortures inflicted upon sufferers from cancer, and many other incidental effects of quackery which are only too familiar to the medical profession, receive, more or less, the condemnatory notices to which they are entitled.

On the whole the report serves to exhibit, in a striking manner, the propriety of the original request of the General Medical Council for the appointment of a Royal Commission, the only body by which the truth in relation to the subject could by any possibility be brought home to the comprehension of the public, and before which the accuracy of such statements as those made by the medical officers of health could be investigated and established. A belief in quacks and quackery is by no means confined to the poor and the illiterate, and its prevalence is one of the consequences of systems of education in which, as FARADAY said, the cultivation of the judgment has been almost wholly neglected. It is possible that the sale of proprietary medicines is largely among the comparatively well-to-do, for it is manifest that the expense incurred in advertising them can only be rendered remunerative by an extensive sale at high prices, although it is well known that the drugs contained in them are seldom as expensive as the wrapping paper in which they are put up, and that the claims made on their behalf are absolutely without a shadow of foundation. When the quack business advertised as "Munyon's" first raised its head in this country, it was announced that a qualified medical man attended at the office, and that he read and considered the letters in which applicants described their symptoms, in order that he might instruct the packers which of several patent "remedies" they were to send in every case. There actually was such a person (one HART) who, in May, 1898, was consequently removed from the Medical Register for infamous conduct in a professional respect. When his case was heard by the General Medical Council he made a frank confession, from which it appeared that if he took the trouble to read the letters he did not know what the "remedies" contained, or what effects, if any, they were calculated to produce. All this was made public; but years later, under the management of the late Mr. CRIPPEN, who was not amenable to the jurisdiction of the Council, the business was still a going concern, and as far as we know the exposure had little or no effect upon the sales. We have to deal in the matter of quackery with a very easy and lucrative trade; and the willingness of the public to be deceived is such that revelations of the mendacity and greed of the advertising charlatan have but little effect upon the fortunes of that charlatan. The matter is one that well deserves the institution of a Royal Commission, upon which possibly some such legislation might follow as is about to be introduced in Germany.[2]

Annotations.

"Ne quid nimis."

THE ITALIAN CONGRESS ON SEXUALISM.

CONSIDERATIONS, significant alike in their number and their gravity, give special interest to the Congress just held at Florence, "Sulla Questione Sessuale," that is, on the relations of the sexes and their bearing on society. The Congress is the first of its kind yet held in Europe, and its seat is the central city of the Italian kingdom; facts, both of them, intimately connected with the progress of the Latin civilisation and the deteriorating influences to which that civilisation has long been subject. For what is true of Italy is in well-nigh equal measure true of France, both nationalities being confronted with the same problem, how to purify the moral life and how to antagonise the forces which are telling disastrously on the population physically, mentally, and economically. While in the French Chamber the Minister of Grace and Justice, in answer to pressing interpellations, has had to pledge the Government to active measures for the protection of the youth from the enervating literature which panders to lasciviou ness and precocious vice, in the Italian Chamber the Premier, who is also Minister of the Interior, has taken the initiative in penalising the production and sale of that literature, with results already apparent in all the great centres of population, saved as these now are from the spectacle of children of tender years gloating over prints and letterpress appealing to the worst passions. As first steps in a salutary direction these measures are, indeed, meritorious; but they are only the beginning of a reform which must be carried far wider and higher in the social sphere. It was this further development of what may, for convenience, be called the "Anti-sexual Crusade," that engaged the Congress which has just closed its sittings in Florence, and if the "orders of the day" in which the discussions culminated were, at best, but indications of policy, educational and administrative, this much may be said in their favour, that they represent a keen and intelligent appreciation of the evils to be grappled with, and that they formulate recommendations, tentative indeed, and even crude, but eminently useful as suggestive of the duties of the State in the school, in the factory, and in the field. The senator Dr. Pio Foà, of the Subalpine Medical

[2] See p. 1650.

School, opened the proceedings with a paper on "La Pedagogia Sessuale." Starting from the principle that—

"Just as the twig is bent, the tree's inclined,"

he insisted on an early inculcation on the juvenile understanding of the physical constitution, of what "being born" means, of what powers the youth is endowed with, of the responsibilities these imply, and of the dangers of their abuse. This instruction, he contended, should not only come from the mother of the family, but should be conveyed by the schoolmaster or the schoolmistress, who, themselves adequately trained for the duty, can be trusted to use their discretion and their tact according to the young pupil's character, moral and intellectual. From this early or initiatory inculcation Professor Foà would proceed, before the pupil's leaving the higher school and entering on life or on special study, to medical instruction, which, conformably to his experience, can be "popularly" conveyed without infringement on delicacy, while imparting all the youth ought to know, for his own guidance, without needless detail. In association with this, the teacher, male or female, could show the evils of kindred indulgences such as alcoholism, and the results of all animal vice in physical deterioration, leading, for example, to tuberculosis or to one or other of the many neuroses which, in Italy especially, fill the police reports with incidents more or less criminal. These positions of the Subalpine consultant were mainly uncontested by the other interlocutors, except by some who insisted on the instruction being left to ecclesiastics—a recommendation which carried the discussion far afield, and raised the objection that an order vowed to celibacy was certainly not the best medium for conveying the lessons required. Recalled from this digression, the Congress proceeded to the consideration of the factors conducive to the immoral life, particularly in the great industrial centres where the young of both sexes are herded together in an atmosphere, moral as well as material, directly provocative of "animalità," or sexual desire, aggravated, moreover, by the poverty which forces families to live under the narrowest conditions as to space and detachment—a promiscuous crowding which blunts the moral sense and robs vice of half its shame. The turn thus given to the discussions brought the Malthusian doctrine to the front, and this again to the Nemesis that always overtakes the non-natural restriction of families. But by this time the more practical of the topics on the agenda paper had had the preponderance, and the Congress rose after carrying an order of the day fixing Milan as the seat of its next meeting, and nominating a committee, with Professor Foà at its head, for the formulation of a programme in continuation of discussions now seen to be of urgent interest, not in the Latin countries only, but in those of the other civilisations, Teutonic and Slav.

PROTECTION AGAINST TUBERCULOUS MILK.

THE model clauses on the subject of tubercle, in force in several of our large towns, contain *inter alia* a requirement that any dairyman supplying milk within these towns and who has in his herd a cow "affected with, or suspected of, or exhibiting signs of tuberculosis of the udder shall forthwith give written notice of the fact to the medical officer" of the town in which the milk is sold (whether the dairy be within or without the city), "stating his name and address and the situation of the dairy or premises where the cow is." A farmer near Leeds was recently prosecuted by the sanitary authority and a conviction was obtained for not having furnished this notice in regard to a cow in his herd which was suffering from tubercle of the udder. In regard to cows kept within the city it is the practice of the Leeds authority to have them examined by a veterinary surgeon in regard to the conditions of their udders, each dairy being thus visited some four times a year. This power of visiting and examining the cows in the herd only applies, however, to dairies within the city unless the medical officer has reason to suspect the existence of tubercle in the milk-supply. In the case of the particular farmer referred to, a specimen was taken of the milk supplied by him within the city early in July, and found to be infected with tubercle, and it was ascertained that a cow in the herd was suffering from a tuberculous udder, a fact which had not been reported to the medical officer of health. This is the second successful prosecution for non-notification of a tuberculous udder which has occurred in Leeds under the model clauses. The earlier case was that of a farmer within the city who had failed to notify the condition of his cow. The importance of a prosecution of this kind, especially where the milk is supplied from an outside farm, lies in the circumstance that great difficulty is experienced in detecting the presence of tuberculous cows in herds outside the city if assistance be not given by the farmers. In the present case the discovery was accidental and many weeks elapsed between the taking of the sample and the discovery of tubercle, and it is eminently desirable that a skilled examination should be made at once of any cow showing signs of tubercle of the udder. We are informed that had the farmer notified the condition as soon as he purchased the cow he would have obtained, without cost, expert assistance; and had the condition been only suspicious he would probably have been compensated by the corporation for any loss of milk due to the isolation of a cow with a possibly healthy udder. Such compensation is frequently made in Leeds when the diagnosis of tubercle of the udder is still uncertain, the corporation preferring to keep any suspected cow out of the milk herd until it is assured that the disease is not tuberculous. Under the present law it is only cows that have tuberculosis of the udder which can be excluded from the milk herd. The third interim report of the present Tuberculosis Commission shows clearly that a tuberculous animal, not suffering from manifest disease of the udder, may from time to time yield milk containing tubercle bacilli.

OPHTHALMIA NEONATORUM.

SINCE our previous remarks on this subject[1] a report recently received from the medical officer of health of the borough of Paddington provides further and welcome evidence of aroused interest in the subject amongst the public bodies concerned. Still more striking is the decision of the London County Council at its meeting on Nov. 8th to enforce the powers granted by the Public Health (London) Act (1891), making ophthalmia neonatorum compulsorily notifiable within the administrative County of London. In this most essential respect London is but following the example initiated in the Potteries, chiefly through the agency of Mr. H. H. Folker, and widely followed in more than 50 sanitary districts in various parts of England. Dr. R. Dudfield's report to the public health committee of the borough of Paddington contains an admirable *résumé* of the subject, cogently setting forth the need for notification and more efficient treatment on the basis of statistics derived from recent literature, but Mr. Sydney Stephenson's excellent monograph on Ophthalmia Neonatorum seems to have escaped attention, for it is not quoted in the scanty bibliography appended to the report. Notification in this disease is attended by peculiar difficulties which are well set forth in Dr. Dudfield's own words: "Notification to be complete must be on a different system to

[1] THE LANCET, July 23rd, 1910, p. 245.

that in force for the dangerous infectious diseases, with respect to which a doctor's certificate is the only form in practical use. Confinements being attended by three classes of persons, (*a*) medical practitioners, (*b*) certified midwives, and (*c*) 'handy women' and relatives, it is necessary that the duty of notification should be imposed on any person—irrespective of status and training—attending the mother during and after her confinement. In other words, the notification system should follow the lines of the Notification of Births Act rather than those of the Public Health Act. The change in system should not deprive professional men (and women) of their fees for certificates. Inasmuch as cases of ophthalmia neonatorum would under such system be reported by lay persons, the description of the disease must be in simple terms and be so framed as to cover even the (apparently) slightest and simplest form of eye trouble. Anything short of such a wide definition would result in cases of ophthalmia in children not under the care of a medical practitioner or certified midwife being unreported, and a plea of ignorance of the nature of the disease being put in by the 'handy woman.' It is among the cases attended by the last class that the disease is most likely to occur. Further, such notification should not involve all the restrictions imposed with respect to the dangerous infectious diseases by the Public Health (London) Act, 1891. Such principle has already been recognised with regard to measles and pulmonary consumption." The difficulties of efficient treatment are even greater. That they are well worth facing and combating is shown by the statistics of Mr. E. V. Greatbatch, chairman of the North Staffordshire Joint School Authority for Educating Blind and Deaf Children. In the five Pottery towns and Leek 75 cases were reported in the nine months to the end of last June. Of the 75 infants 61 recovered with full sight, 7 lost one eye each, and 2 became totally blind. Mr. Greatbatch points out that "an average blind person cannot earn more than one-half of the amount earned by a sighted person at the same occupation," and Lord Lichfield has estimated the cost of education of a blind child at £50 compared with £30 for the education of a normal child. These figures tell their own story, and the day cannot long be distant when the disease will be universally notified.

THE CHILDREN OF THE STATE IN HUNGARY.

THE methods employed in Hungary for the care of those who would be termed in England "pauper children" may be commended to all interested in social reform, and in particular to local administrators concerned with the care of children and the feeble-minded. It is always a shock to British pride to find ourselves distanced in the race for better social legislation, and to those unacquainted with Hungary it may come as a surprise to find existing in that country a system of public care for destitute children conceived in a spirit above anything as yet achieved in England. The class of children for whom provision is made appears to include not only those who in our country come under the head of "destitute," but also the permanent cripples and feeble-minded, idiotic, and the morally defective. The number of children dealt with is not large, but is rising rapidly; in 1903 it was 21,000 and in 1908 it was 44,000, out of a total population of about 20,000,000. The scheme adopted divides the country into 17 administrative centres, or "asiles," which are placed in large towns. Each centre includes homes or hospitals for acute cases, for chronic cases, and for sucklings, while in Budapest and one other city are small hospitals for operative surgery and for ophthalmic cases. With these exceptions all the asylums are constructed on the same model with trifling variations in plan and arrangement. Each has a non-medical executive head, who is responsible for the finance of the centre, and under him a steward. A controlling physician is attached to each, having an assistant who is usually a lady doctor. The children who are not invalided or otherwise disqualified are boarded out as soon as possible. This is effected in selected villages under selected foster-parents without regard to locality of birth or distance. The children and their custodians are carried free on the State railways in reserved compartments over a network of more than 15,000 miles of rail, and in 1908 over 46,000 tickets were issued for this purpose. The executive in each centre supervises the colonies strictly, and provides carefully for the future of each child on his discharge from tutelage. Each child on admission to the "asile" is accompanied by a schedule of health, including such particulars as previous mode of nourishment, condition of vaccination, and other particulars; the family history furnishes not only statements as to such ordinary points of inquiry as syphilis, insanity, or tuberculosis, but contains remarks as to hereditary neurasthenia, perhaps the first official recognition of "Weary Willie" as an important hereditary factor in the State. This contrasts strangely with the haphazard lack of information afforded to district medical officers in most unions in our country when they first visit boarded-out pauper children. The care exercised in the selection of wet-nurses, and the provision and control of milk, are also admirable examples of minute method.

OBESITY IN RELATION TO DISEASE OF THE DUCTLESS GLANDS.

THE question of the functional interrelation of the various ductless glands is curiously complex. It is scarcely an exaggeration to say that with the publication of each fresh clinical record our uncertainty is increased rather than diminished. One writer describes a pineal "syndrome" of changes in the body tissues and sexual impairment associated with a pineal tumour; the next reported cases of pineal tumour reveal no such changes. A number of cases of sexual infantilism in connexion with pituitary disease have been recorded, but precocious sexual development related to disease of the adrenals seems equally substantiated. In view of all this uncertainty certain writers have begun to describe "polyglandular syndromes" as though our knowledge were thereby added to. Analysis must precede synthesis. Let us take for examination the question of abnormal development of fat, both subcutaneous and within the body cavity. Many women become stout after the menopause, and superficial consideration will at once associate this change with defective ovarian secretion. As if to bear out this view, we remember that many domesticated animals put on fat after castration, especially the female. This is true in particular of the cow (Charlier). Further obesity after ovariotomy is well enough known (Strümpell). Launois and Cleret, on the other hand, have recorded a case of adiposis associated with precocious sexual maturity, and in this instance the temptation is to assign the change to some suprarenal defect. Again, we know that, apart from the subcutaneous changes that characterise myxœdema and give it its name, there is often an abnormal increase of fat, and the attribution of myxœdema to thyroid deficiency meets with universal acceptance. The condition of so-called "feminism" in the male, where the secondary sexual characteristics are those of the opposite sex, including abnormal development of the breasts and of subcutaneous fat, undoubtedly occurs where there is reason to suspect pituitary changes, but many of these patients have double testicular atrophy. Is this a cause or a consequence? The fact is that medical science has simply touched the fringe of the subject. Thyroid, testicle, ovary, suprarenal, and pituitary in turn seem to be incriminated. Yet we cannot

overlook the fact that it is more particularly in pituitary disease that fatty changes are to be expected. Launois and Cleret have published an interesting case in point. A woman, aged 33 years, enormously stout, with cyanosis of the face and hands, menstrual irregularities, and certain cerebral symptoms, was found post mortem to have a small tumour of the pituitary body involving the glandular part of the organ; the nervous part was normal. The tumour was an epithelioma consisting of acidophil, amphophil, and basophil cells, with others badly staining and others still atypical, voluminous, and multinuclear. There was no acromegaly. To attribute the obesity to the results of this tumour growth is, of course, most natural, but the thyroid was sclerosed and in a state of hypothyroidism, while the ovaries were also sclerosed and cystic. There are numerous recorded instances of "degeneratio adiposo-genitalis" (distinct from "feminism") in pituitary disease, but is the adiposis secondary to the hypophyseal or the testicular defect, or to both? Perhaps the least equivocal case is one due to Madelung. A perfectly normal and healthy child, aged 6 years, was shot in the head at a distance of 8 or 10 feet and fell unconscious. After four days of coma consciousness began to return. Shortly thereafter she began to show certain psychical symptoms, and, in addition, to put on fat rapidly. Three years later she was very fat indeed. X ray examination showed clearly that the projectile was lodged in the sella turcica. If we may argue from this case we may assume that obesity may certainly be of primary hypophyseal origin, and where the lesion is polyglandular perhaps there is a reciprocal disturbance of metabolic balance, so that it becomes difficult, if not impossible, to assign the clinical symptoms to direct defective function of any one gland in particular, at least until much more is known of the subject.

INFANTILE BERI-BERI.

MUCH light has recently been thrown upon the etiology of beri-beri by the researches of Fraser and Stanton in the Federated Malay States and by other investigators elsewhere; but a new problem in connexion with this disease has recently been raised in a paper read at the biennial meeting of the Far Eastern Association of Tropical Medicine, and published in the July number of the *Philippine Journal of Science*, by Dr. Allan J. McLaughlin, assistant director of health for the Philippine Islands, and Dr. Vernon L. Andrews, assistant professor of bacteriology and pathology in the Philippine Medical School. These observers have been making a study of the causes of the excessive infantile mortality in Manila, and their inquiries have led them to the conclusion that a large number of infants die from a disease presenting a definite pathological picture for which they say no better name can be given than "moist beri-beri." The total deaths certified from this cause in children under one year of age in Manila for the fiscal year 1908–09 amounted to 595. But this does not, it appears, represent the full mortality from the disease. Post-mortem examination of a number of cases certified as due to convulsions, bronchitis, and broncho-pneumonia demonstrated that the cause had been wrongly given and that death was due to "moist beri-beri." In a series of 219 necropsies on infants dying under one year of age no fewer than 124 were found to present the characteristic appearances of this disease. The main post-mortem conditions observed were: (1) dilated and hypertrophied right heart; (2) congestion of all internal viscera; and (3) anasarca. The investigators did not themselves see the cases during life, but were dependent on others for the clinical histories, which, however, in a number of instances were meagre and not always trustworthy. The symptoms noted were chiefly dyspnœa and cardiac embarrassment with general œdema. The illness was said in some cases to have lasted only a few hours, seldom more than two days, but it is possible that the ailment had existed longer than this, perhaps from birth. It is a very noteworthy fact that nearly all the cases examined were under two months of age, and, what is still more surprising, they were almost without exception *breast fed*. It is distinctly stated that in none of the cases in which a necropsy was made was any rice or other artificial food found in the baby's stomach. In nearly every instance the mothers themselves presented some symptoms of beri-beri, and a number of them admitted that they had already lost other infants who had suffered from a similar illness. The etiology of "moist beri-beri" has not yet been fully investigated, but there seems to be some suggestion that a relationship exists between this malady and the poor quality of the milk yielded by Filipino mothers. This condition of the mother's milk, which is probably deficient in certain essential elements necessary for the normal nutrition of the infant, is due no doubt to the physical condition of the native mother, who, as a rule, lives in chronic poverty with consequent insufficiency of proper food, more particularly during the periods of pregnancy and lactation. Nevertheless, Dr. McLaughlin and Dr. Andrews say that they cannot overlook the possibility of an ultra-microscopic organism being concerned in the production of the disease. It is, however, proposed to make further investigation into "moist beri-beri," with detailed clinical observation of cases, preferably in hospital, where laboratory and biological tests can be readily applied, and where examination of the patient's body fluids and excreta can be carried out. Although the occasional occurrence of beri-beri in infants is mentioned in works upon the disease, we gather that this has hitherto been regarded as rather exceptional. Some ten years ago Professor Hirota of Tokyo described a disease discovered by him in infants brought to his clinique for treatment, and which he named "infantile beri-beri." The native medical practitioners in Manila appear to have become acquainted with the views of the Japanese professor and during the past few years have been certifying deaths as due to this cause. The ailment, we learn, is not often seen by the American physicians in the Philippine Islands, since the poor people are attended, if attended at all, by Filipino medical men exclusively. So far as we are aware no attempts have been made, until the inquiry undertaken by Dr. McLaughlin and Dr. Andrews, to confirm the diagnosis of infantile beri-beri by post-mortem examinations. It is greatly to be hoped that the further inquiries which are to be carried out will succeed in elucidating the etiology of this form of beri-beri, which has become so disastrous a factor in the excessive infantile mortality met with in Manila.

PUBLIC HEALTH IN SHANGHAI.

Dr. Arthur Stanley, medical officer of health of Shanghai, draws attention in his annual report to the municipal council of Shanghai for 1909 to the satisfactory state of the public health for the year. The native population was calculated at 550,000, and the foreign population for the same period was calculated at 15,000; the death-rate among the former per 1000 during the year was 15·1, and among the latter 16·7. Tuberculosis heads the list of fatal diseases both among foreigners and natives and calls for a measure reducing the overcrowding which is so apparent in the settlement. Beri-beri is now a prominent cause of death among foreigners, coinciding with the increased Japanese population. Plague-infected rats were found throughout the year, but there were no human cases. The public measures most needed are an extension of the health office and laboratory buildings; the completion of the

isolation hospital to include accommodation for cases of tuberculosis among foreigners; and the establishment of health stations in each sanitary sub-district. The Shanghai Pasteur Institute for anti-rabic treatment has done good work; since it was opened in 1899 268 persons have received treatment; during the year under review 28 cases have been treated with success. The hospitals have all been satisfactory. The police hospital for the Sikh police from India reports that tuberculosis continues to be the commonest cause of invaliding out of the service. Venereal disease accounts also for a relatively large proportion of the sickness occurring in this force.

THE TREATMENT OF AORTIC ANEURYSM BY THE INTRODUCTION OF WIRE AND THE PASSAGE OF A GALVANIC CURRENT.

THERE are few morbid conditions which seem less open to heroic treatment than aneurysm of the thoracic aorta. Any direct attack upon so formidable a disease of so vital a structure appears only to invite disaster. Nevertheless, the desperate nature of the malady offers some justification for the adoption of any method of treatment which holds out a prospect of substantial improvement in the patient's condition. Doubtless it is this motive which has led physicians to take the risks that are involved in the introduction of wire into the sac and the passage of a galvanic current through the wire. Professor A. A. Eshner has been able to collect and tabulate records of no less than 36 cases in which this treatment was adopted, in addition to two cases of his own, which were published in the *American Journal of the Medical Sciences* for October. He considers that in the vast majority of these cases the intervention was justified by prolongation of the patient's life and amelioration of symptoms. It is contra-indicated in fusiform aneurysm. The technique, he says, is simple; in his cases, as apparently in other cases, local anæsthesia sufficed. Under aseptic conditions a hollow needle of gold, silver, or platinum, insulated except at its tip, is introduced to some depth into the most prominent part of the sac, and through this gold or silver wire is fed into the sac till it is filled. Usually 10 or 12 feet of wire will suffice. Should the wire kink before the sac is full the needle may be withdrawn and re-inserted in another place, or one or more additional needles may be used. The end or ends of wire are connected with the positive pole of a battery, the cathode being placed upon the back; a current rising gradually from zero to 60, 80, or 100 milliampères and as gradually decreasing is then passed through for an hour to one and a half hours. The hæmorrhage is limited to a spurt of blood at the introduction of the needle. Pulsation is noticed to diminish with the passage of the current, if not before, and a similarly immediate relief from pain and dyspnœa is experienced. From Professor Eshner's table it appears that in 19, or exactly half the cases, death followed within a month of the wiring, the best result being that obtained by Professor Rosenstirn, whose patient lived nearly 12 years after the operation. One of Professor Eshner's own patients lived four weeks, the other a little over seven months. In both cases post-mortem examination seemed to prove that the operation had not only done no direct harm, but also that it had very materially expedited the progress of clotting within the sac. The impression left upon the mind by a perusal of Professor Eshner's careful tabulation is that the method will never have a wide field of usefulness, and that its use is scarcely justifiable except in cases of sacculated aortic aneurysm so far advanced that there is no hope of spontaneous cure.

FREIBANK MEAT.

THE December number of the *Contemporary Review* contains an article on "Cheap Meat," which is likely to attract considerable attention at the present time. The writer, Miss Smith Rossie, there tells of her observations at a German Freibank, and gives forcible expression to her dislike of the kind of meat which she understood to be sold at these establishments. We have no concern with the political purpose of the article, but we would suggest that it would be well for those whom it interests to study any good account of the general system of meat inspection in Germany before following Miss Rossie too far in her commiseration with the poorer classes in Germany by whom such meat is eaten. The provision of Freibanks is not essential to the imperial meat inspection system, although they have been established for many years in a considerable number of German towns. At the public abattoirs of these towns, meat which after examination is judged to be only conditionally fit for food ("bedingt tauglich") by reason of disease not calling for total condemnation, together with certain meat of poor quality, passes to the Freibank for special sale. Before the diseased meat is allowed to be sold it is treated, as circumstances require, by removal of diseased portions, by prolonged freezing and salting, or by sterilisation in digestors. From the last annual return of meat examined in the slaughter-houses in the German Empire, it would appear that less than 0·5 per cent. of the total meat dealt with was classed as "bedingt tauglich." Although Freibank meat is readily sought after by many people of the poorest class in places where it is available, it must not be regarded as the staple or even as a usual food of the German working class in general. Probably many working class families in Germany share Miss Rossie's aversion to eating meat derived from diseased animals, no matter how it has been treated. The existence of such natural objections, however, is fully recognised by the German law, which makes stringent provision against the sale of Freibank meat to restaurant-keepers, sausage-makers, and other traders, and prevents it from becoming an ordinary article of commerce. The consumer must fetch it from the Freibank, and need not go there unless he chooses. As regards the wholesomeness of Freibank meat, it may be said that where, as generally in Germany, a sufficient staff of trained experts is employed, and the arrangements for handling and treating the meat are efficient, the danger run by the consumer must be of very small proportions. It is impossible, perhaps, to say that it is entirely removed. It must, for example, often be doubtful whether meat sold without sterilising after removal of tuberculous lesions is in reality free from infective ability, while in the case of meat which is sterilised it is still sometimes necessary to remember the possible presence in the meat of bacterial toxins which are highly resistant to heat. Under English administration practically all meat of the "bedingt tauglich" order which came under the notice of our sanitary officers would be condemned outright, and if we examined all our meat and discovered disease in it with the thoroughness of the Germans, we might congratulate ourselves that we have no use for a Freibank, and that the poorest of our population would probably be strongly prejudiced against such an institution. Unfortunately, however, there are facts concerning the disposal of diseased meat in this country that will not allow of such complacency. From the public health point of view, diseased meat which in England may reach the consumer by way of the "slink" butcher or dealer is hardly to be preferred to that which in Germany is sold openly and as a class apart after expert examination and treatment.

GANGRENE OF AN OPERATION WOUND DUE TO THE COLON BACILLUS.

A MILD infection of an operation wound with the colon bacillus is not of infrequent occurrence in abdominal surgery. In the *Journal of the American Medical Association* of Oct. 29th Dr. E. A. Babler has reported a case, which so far appears to be unique, in which necrosis was due to this cause. A man, aged 45 years, was admitted into hospital on May 14th, 1910. He had suffered frequently from malaria. Three days previously, while tying his shoe, he was seized with a stitch in the right side, and the pain had been more or less persistent since the onset. On the next day he had a chill which was followed by fever. On admission he complained of severe pain in the region of the right ninth intercostal space. He was anæmic and emaciated and had an anxious expression. The respirations were somewhat shallow and accelerated. There was a slight cough, which caused pain in the right side. Over the right axilla harsh inspiration and blowing expiration were heard, and throughout the chest numerous dry râles. Vocal resonance and fremitus were increased over the middle and lower lobes of the right lung. A friction rub was heard close to the right costal margin on both inspiration and expiration. Over the lower lobe of the left lung there was relative dulness. On May 16th a leucocyte count gave 19,100, and on the 30th 24,800. On June 5th the number had dropped to 10,700. There was bulging in the right hypochondrium. On June 23rd subphrenic abscess was diagnosed, and on the 24th an incision 2 inches long was made under cocaine anæsthesia in the anterior axillary line over the most prominent part of the bulging mass, and about two quarts of fluid resembling the pus of a hepatic abscess were evacuated. The abscess was found to be subphrenic, although the palpable liver surface was roughened. The pus contained the colon bacillus in pure culture and showed no liver cells. A double drainage-tube was inserted. The discharge from the wound was profuse. On July 18th the margins of the wound became very red and somewhat swollen. The inflammation spread. On the 23rd the margins of the wound became necrotic and discharged grumous substance, which yielded a pure culture of the colon bacillus. On August 10th an autogenous culture of the bacillus was injected, but was followed by a rise of temperature and seemed to make the patient worse. The area of skin destruction became more and more extensive until at the time of death, which occurred two months after the operation, an area of the size of the palm was involved. At the necropsy it was found that the floor of the abscess was formed by the base of the liver and the roof by the base of the lung. The greater portion of the intervening diaphragm was destroyed.

HELIOTHERAPY IN TUBERCULOSIS.

IN an annotation in THE LANCET of Nov. 12th, p. 1435, we called attention to the remarkable results obtained by heliotherapy (the prolonged exposure of the diseased part to the sun's rays) on the Mediterranean littoral. In the *Boston Medical and Surgical Journal* of Oct. 27th a special correspondent contributed an interesting article which shows that similar results can be obtained in the Swiss mountains. At Leysin, which has an altitude of 1200 to 1500 metres, Dr. Rollier has established three sanatoriums and attained results which have attracted widespread attention. This locality has certain peculiarities which render it unusually suitable for heliotherapy—absence of wind, intense solar radiation, and great purity of air. Having found that Dr. Bernhardt of Samaden in the Engadine was treating sluggish wounds of all sorts by solar radiation, Dr. Rollier began little by little to apply this method to the treatment of surgical tuberculosis, and has found it to be successful. The majority of the patients are children suffering from fungous arthritis, Pott's disease, tuberculous arthritis, tuberculous glands, and tuberculous lesions of the skin. Dr. Rollier does not neglect the usual methods of treatment—injections, plaster jackets, X rays, and so on, but combines them with heliotherapy. His sanatoriums face the sun and are abundantly provided with balconies and open roofs on which the beds are wheeled out. The patient's entire body, front and back, is exposed to the sun in winter as well as in summer, during a time which varies with the state of health and state of training. The patient must be apyretic or nearly so. Dr. Rollier begins by exposure of short duration. The period and extent of the exposure are gradually increased until the whole body is exposed for as much as six or seven hours daily. The startling sight may be seen of a lot of naked brown children, some wearing plaster jackets, playing on beds in the brilliant sunshine in midwinter. Hats and screens are used to keep the sun off the face. Even in winter the temperature in the sun is high (113° to 122° F.). Moreover, there is almost total absence of wind. But for this the treatment probably could not be carried out. One of the first results of heliotherapy seems to be the disappearance of the pain—in coxalgia, for example. Tuberculous glands are either absorbed spontaneously or soften, and after one or two evacuating punctures disappear. Dr. Rollier argues that for heliotherapy a mountain climate is much preferable to the lowlands, where many of the sun's rays are absorbed by the dust of the atmosphere. In spinal or hip disease the surgeon generally regards ankylosis in a good position as the best result, but Dr. Rollier claims to obtain a restitution *ad integrum* with free movement. This is obtained even in some cases of open lesion in adults. It must be borne in mind that the treatment is a prolonged one and may take two years or more.

THE Edward Medal of the Second Class has been awarded to Mr. Edwin Arthur Dando, M.R.C.S. Eng., L.R.C.P. Lond., for courage shown on the occasion of the underground fire which occurred at the Russell Colliery, near Dudley, on April 17th, 1910.

THE Bradshaw Lecture of the Royal College of Surgeons of England will be delivered on Wednesday next, Dec. 7th, at 5 P.M., in the theatre of the College, by Sir A. Pearce Gould.

THE discussion on Dilatation of the Heart and Heart Strain, opened by Dr. J. F. Goodhart with the paper which we publish this week, was adjourned until Monday next, Dec. 5th, at 8.30 P.M., when it will be resumed by Dr. William Collier, of Oxford, followed by Dr. Samuel West, Dr. A. Morison, Dr. F. J. Poynton, Sir John Broadbent, Dr. C. W. Chapman, Dr. F. Parkes Weber, and Dr. Leonard Guthrie.

THIRTY-SECOND BALNEOLOGICAL CONGRESS, BERLIN.—This congress will be held in Berlin from March 2nd to 6th, 1911. Several papers have already been promised by well-known authorities in balneology. It is requested that notifications of further papers which it is intended to offer should be sent before Dec. 31st, 1910, to the Secretary-General Geheimrat Dr. Brock, Berlin, N.W., 52, Thomasiusstrasse, 24. The meetings of the congress will take place in the lecture-hall of the Polyclinic Institute of the University, Ziegelstrasse 18/19. In connexion with the congress there will be an exhibition of medical apparatus and preparations.

THE LONDON COUNTY COUNCIL AND A SLUM CLEARANCE SCHEME.

THE London County Council to-day has few graver problems to deal with than the housing question, which was first propounded by philanthropists in the middle of the last century. As matters stand, the value of house property and building sites in those central, overcrowded, and insanitary districts which we classify as slums has increased, and is increasing, with the result that such work as has been done in purchasing, demolishing, and rebuilding has been costly and has not brought any direct profit to those charged with it. At the same time, every improvement accomplished, however long delayed it may have been, is a matter for congratulation. The London County Council having abstained from carrying out any clearance schemes for nine years has now put itself in a position to face the struggle again, and should do so with the support and goodwill of London's citizens, although we may be allowed to call attention to the long period of consideration which has preceded action.

The Areas to be Dealt with.

At a meeting of the Council which was held on Nov. 8th a scheme for the Housing of the Working Classes Committee was brought up and agreed to after some discussion; it provided for the clearance of the slum areas known as Tabard-street and Grotto-place, Southwark, and Crosby-row, Bermondsey. It is proposed that the Council should acquire 13½ acres, mainly to the north of Tabard-street, 1½ acres constituting the Grotto-place area, and about an acre on the east side of Crosby-row; that the buildings now standing should be cleared away, that about 5 acres of the Tabard-street area should be reserved from building and maintained as an open space, that another portion of the available ground should be let for commercial purposes, and that on the residue should be erected dwellings capable of accommodating not less than 2450 persons. Some interesting facts were referred to by Major Boscawen, chairman of the Housing Committee, in introducing the scheme. The expenditure of the Council and of its predecessor, the Metropolitan Board of Works, upon clearances of a similar kind has amounted to £2,440,000, of which the sum of £1,349,000 remains as a debt. The slums which form the subject of clearance schemes do not exist, as a rule, on the estates of the great landlords who are so frequently denounced by popular orators in this connexion, an example in support of this being found in the comparatively small areas described above which are divided up among 105 freeholders and 60 leaseholders. The following figures were cited by Major Boscawen with regard to the Tabard-street area upon the authority of Mr. Charles Booth. The proportion per cent. of those living in comfort and in poverty respectively is estimated for the whole of London at 69·3 in comfort and 30·7 in poverty; for the whole of Southwark the corresponding figures given are 52·4 and 47·6, a balance being still left on the side of comfort. The Tabard-street area, however, has 80·9 per cent. of its inhabitants living in poverty and in comparative comfort only 19·1. Its death-rate at the time of the compilation of the statistics given was 36·8 per 1000, as against an average of 14·9 for the rest of London, its death-rate from phthisis being 3·88, as compared with London's 1·44; and its death-rate from infectious disease was estimated by the same statistician to be six times greater than that of London.

In these circumstances it may well be understood that the Council, having had a scheme laid before it by its responsible committee, determined to proceed with it at once without waiting for such possible variations of price and depreciations of estimated value as may be expected to result from recent financial legislation. We note, however, that Sir John Benn, while he disavowed any desire for delay in dealing with the plague spot under the Council's consideration, expressed the opinion that the new valuation, had it been waited for, would have reduced the price to be paid by £100,000. If this estimate be at all correct, the measure referred to will at least facilitate the rehousing of the poor.

We note that one of the county councillors who took part in the discussion of its Housing Committee's report attributed blame to the sanitary authorities of the districts involved for the conditions rendering drastic interference necessary. Certainly the Southwark borough council has been fully informed through the reports of its medical officer of health for many years as to the insanitary state of the slums about to be swept away, and the London County Council has also no doubt had the same source of information open to it. We find, for example, pointed reference to Grotto-place in the report made by Dr. F. J. Waldo, since appointed coroner for Southwark, so long ago as 1897. Its courts are so narrow that the inhabitants of opposite houses can shake hands with one another by leaning out of their front windows, and he then classified it as an unhealthy area, together with two other sites known as King's Bench-walk and Webber-row. Some of the buildings then and now objected to were formerly one-roomed houses, since converted by partitions so as to consist of two rooms, which originally were built for the accommodation of debtors committed to prison by the Court of King's Bench. In or about 1900 the London County Council dealt with King's Bench-walk and Webber-row, but left Grotto-place untouched on the ground that its death-rate was not so high as that of the other two districts. In 1900 also Dr. Waldo had under consideration for purposes of reform a group of streets, including part of Tabard-street, all of which have hitherto escaped interference. At the same time, if his reports dealing with Tabard-street, Grotto-place, and their surroundings have not borne fruit hitherto, he may take credit for having initiated in 1894 the policy which got rid of the slums once known as Brent's-court, Eve-place, Redcross-court, and Maypole-alley, and for the opening of Little Dorrit Playground for children opposite to the site of the old Marshalsea Prison upon the ground once occupied by Falcon-court and Birdcage-alley.

How the Sites will be Utilised.

The question of how sites so expensively acquired are to be utilised is one of some difficulty. They can be made into open spaces, workmen's dwellings of a sanitary character can be built upon them, or they can be let for commercial purposes and at a rent proportionate to their commercial value. Often there is no open space for use as a children's playground within a mile or two on the one hand, and on the other it must be remembered that a clearance scheme displaces a number of poor persons who go to increase the overcrowding elsewhere.

Presumably it is the more decent people elsewhere inconvenienced by such additional overcrowding who ultimately find their way into the new buildings, for the model dwellings erected upon slum sites do not attract the former inhabitants of the demolished rookeries, and the County Council does not profess to build for thieves and prostitutes, but to provide wholesome living accommodation for those who desire to live comparatively wholesome lives. The converted districts, in short, have to forget their past, although it may be instructive to recall it with regard to some of those named. In 1892 a passage leading to a house, now demolished, which abutted upon Falcon-court, was the scene of the brutal murder of a medical man, Mr. William Peter Kirwan, who was found there dead, having been assaulted and strangled and robbed in broad daylight. Three men were convicted of manslaughter and sentenced to long terms of penal servitude for this crime. In Redcross-court, also mentioned above as having already been reformed, was a common lodging-house, the deputy of which was an ex-convict, and which nightly sheltered at least 100 thieves and prostitutes. The crimes occurring in such a place were almost impossible to bring home to those who committed them. To go back to earlier days, in 1866 the last death from Asiatic cholera occurring in the parish of St. George the Martyr, Southwark, took place in Redcross-court, and it may be mentioned that this parish was credited with 242 deaths from typhus in the years 1863–65, without counting those of its inhabitants who entered hospitals outside its boundaries and died in them.

In such circumstances the duty is to provide a certain amount of decent housing accommodation, including, if possible, some substitute for the street as a playground for the young, and to do so with reasonable regard for the cost of what is done at the ratepayers' expense. The London County Council, as it will be observed, has decided to combine these objects in its latest scheme. It proposes to give an open space, perhaps not so beneficial so far as children are concerned as two of smaller size; to provide dwellings

for a number of persons equivalent to half of those displaced; and to diminish its loss on the transaction as far as possible by allowing the erection of warehouses upon part of the site acquired. We regret the necessity for the warehouses, and we might have desired to see an open space at Grotto-place, but we cannot ignore the need for economy when so much more remains to be done. The more the provision of living and travelling accommodation enables the humbler class of worker to live at a distance from his work the better it will be for his family.

REPORTS ON PLAGUE INVESTIGATIONS IN INDIA

ISSUED BY THE ADVISORY COMMITTEE APPOINTED BY THE SECRETARY OF STATE FOR INDIA, THE ROYAL SOCIETY, AND THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.[1]

The Experimental Production of Plague Epidemics among Animals.

IN two previous series of experiments the Commission showed that healthy guinea-pigs did not contract plague when kept in close confinement with plague-infected guinea-pigs so long as fleas were absent, and that in the presence of fleas the disease readily spread from the infected to the healthy animals. It was objected by Gottschlich that the results did not necessarily apply to rats and could not be used as an argument bearing on the question of the mode of propagation of plague among rats in nature. The present paper details experiments showing that exactly the same results are obtained when guinea-pigs are replaced by rats. Healthy wild Bombay rats were confined in small huts with other rats which had been inoculated with, and subsequently died from, plague; in one hut in each experiment abundant fleas were present, in the other there were no fleas. Considerable difficulty was experienced in securing the complete freedom of the control rats and huts from fleas, but the following results were obtained in eight experiments in which this condition was obtained:—

Results of Experiments with Rats (Inoculated and Uninoculated) put into Huts containing Fleas and into Huts containing no Fleas.

—	Rats put into huts containing fleas (about 24 fleas per rat).	Rats put into huts containing no fleas.
Inoculated rats	70	84
Died from plague	63 = 90·0%	73 = 86·9%
Uninoculated rats	125	125
Died from plague	57 = 45·6%	0

In seven other experiments the control huts were not altogether free from fleas, one or two fleas being found in each. In these 105 healthy rats were exposed to possible infection from 78 rats dying from inoculated plague and only one died from plague. In the corresponding huts in which fleas were more abundant 64 inoculated rats died while living with 105 healthy rats, and of these latter as many as 38 (36 per cent.) took plague and died. These experiments, therefore, support the view that the rat flea is of paramount importance in the dissemination of plague among rats. A few rats dead from plague were eaten in both groups of huts, but the figures show that this was of no account in spreading the infection.

Resolving (Chronic) Plague in Rats.

The abscesses in the viscera, especially in the spleen and in the peripheral lymphatic glands, some of which contain living plague bacilli, which have previously been described as "chronic plague," are shown to be plague lesions in the process of healing; the name "resolving plague" is more appropriate. These appearances have been found frequently in rats in Belgaum and Poona, and a re-examination of Bombay rats shows that they also occur there; they had previously been found only in Punjab villages. It is also shown now that they are found most frequently towards the close of, and immediately after, the acute plague epizootic. The lesions in the spleen and mesenteric glands often ultimately find their expression in peritoneal adhesions. No evidence has been obtained that these abscesses are of actual importance as a source of acute rat plague.

On the Spread of Epidemic Plague through Districts with Scattered Villages.

In large towns, such as Bombay, the infection of plague is carried over from one epidemic to the next by the persistence of acute plague among the rats accompanied by a few human cases. But in small communities each annually recurring epidemic is separated from that preceding by an interval more or less prolonged, in which plague cannot be found in either rats or men. It is obviously an important practical question in such places whether each successive epidemic has its origin from remnants left over *in situ* from the previous epidemic, or whether on each occasion infection is due to plague bacilli being brought in afresh from outside. Towards the solution of this question of "recrudescence" or "importation" a great mass of data has been collected and discussed by Major George Lamb relating to the plague history over a period of four or five years of more than 2500 villages in the Punjab and United Provinces. Dr. Greenwood, statistician to the Lister Institute, contributes the first part of an analysis of these data by statistical methods. Their chief conclusions are: (1) that the occurrence of epidemics among the villages is not a chance distribution; (2) that the size of the village is an important factor, the larger villages being more liable to attack: in two out of the three districts investigated the distribution of epidemics among villages of equal size has not been shown to be other than random; (3) that the fact of a village having been infected in any one epidemic does not render it more liable to be infected in the next following epidemic; (4) that a study of the distribution on maps of infected villages month by month suggests a spreading-out of infection from various centres. On the whole, therefore, the authors conclude that importation is a more important factor than recrudescence in the annually recurring epidemics in these villages.

Observations on Plague in Belgaum, 1908–1909, and in Poona, 1908–1909.

These two papers contain the result of a close inquiry, lasting in each case for a full year, into the occurrence of plague in rats and men in Belgaum and Poona, together with studies of the rats and fleas. The facts collected under the former heads do not lend themselves to summary treatment. With regard, however, to the fleas, it was ascertained that there was a definite seasonal variation in the prevalence of fleas which is closely correlated with the seasonal prevalence of plague. Thus—

Month.	Belgaum.		Poona.	
	Plague deaths, average per week.	Average number of fleas per rat.	Plague deaths, average per week.	Average number of fleas per rat.
January...	9	5·9	22	5·0
February	6	7·7	5	4·8
March	1	5·9	1	4·4
April	0	5·6	1	2·5
May...	0	3·9	1	2·4
June	1	7·4	0	2·2
July	2	14·5	0	4·5
August	9	16·3	2	8·8
September	28	16·9	28	9·1
October...	23	15·2	102	7·6
November	23	13·6	89	7·2
December	19	8·3	46	6·7

These results therefore fully confirm the data already obtained in Bombay, Kasel, and Dhand. The climatic conditions in Belgaum and Poona are quite different from those which prevail in Bombay. This strengthens the conclusion

[1] Journal of Hygiene, vol. x., No. 3, pp. 313-568. Accounts of previous reports will be found in THE LANCET of Nov. 3rd, 1906, p. 1233; July 27th, 1907, p. 246; and Jan. 25th, 1908, p. 253.

that the prevalence of plague depends upon the prevalence of fleas rather than that both phenomena are independently conditioned by circumstances of temperature, &c. The present data suggest a connexion between the atmospheric humidity and flea prevalence. In Belgaum an interesting census was made of the various animals living in the native houses; there was no evidence that cats afforded any protection For the valuable discussions of the causes of the rise and fall of epidemic plague in these towns, the original memoirs should be consulted.

First Report on Investigations into Plague Vaccines (by S. Rowland).

Dr. Rowland, of the Lister Institute, working at Elstree under the direction of the Advisory Committee, has attempted to isolate from plague bacilli the substance which, when inoculated into animals, arouses an immunising response. In a series of experiments conducted by exact methods, he shows that after killing the bacilli with chloroform and drying with anhydrous sodium sulphate a nucleo-proteid may be extracted from the bodies of the bacilli which possesses immunising properties of a high order. A single dose of 0·001 to 0·01 milligramme reduces the mortality on subsequent inoculation with virulent plague from about 70 per cent. to about 13 per cent. The whole bacilli killed with chloroform given in the optimum dose are much less efficacious. The inquiry is still in progress.

Interim Report by the Advisory Committee.

The following statement embodies the chief conclusions which have been provisionally reached by the Advisory Committee as the result of the investigation made under their direction from 1905–09 into the mode of spread of plague in India.

1. Considerable epidemics of human plague consist almost entirely of cases of bubonic plague and are directly dependent on the occurrence of epidemic plague in rats. The development of the rat epidemic precedes the human epidemic by an interval of about a fortnight. There is no evidence that any animals except rats play an important part in plague epidemics.

2. *Epidemic plague in rats.*—(*a*) That fleas which have sucked the blood of a plague-infected rat can transmit the disease to healthy rats to which they are transferred. The plague bacilli multiply in the stomach of the flea, and the flea may be still capable of conveying infection three weeks after having imbibed plague-infected blood. (*b*) If plague-infected rats are kept in close confinement along with healthy rats no epidemic of the disease occurs in the absence of fleas. In the presence of rat fleas the disease spreads from the infected to the healthy animals, and the rapidity and severity of the epidemic so produced is in proportion to the abundance of fleas. (*c*) Rats may be infected by feeding them upon the bodies of other rats dead from plague. The distribution of the lesions in the bodies of naturally infected rats corresponds with that in rats experimentally infected by means of fleas and not with that in rats infected by feeding. The committee, therefore, conclude that *in nature plague is spread among rats by the agency of rat fleas.*

3. *Epidemic plague in man.*—(*a*) Bubonic plague is not directly infectious from man to man as is shown by the experience of plague hospitals where there is no tendency for the disease to spread from the sick to the attendants. (*b*) Material epidemics of plague in man are always associated with epidemic plague in rats. Epidemic plague among rats provides a large number of infected rat fleas, and owing to the mortality among the rats brings these fleas on to human beings. (*c*) Rat fleas (*Pulex cheopis*) bite human beings, especially in the absence of their natural host. (*d*) Rat fleas containing plague bacilli and found capable of transmitting plague to animals may be caught in plague-infected houses. (*e*) Animals susceptible to plague (guinea-pigs, monkeys) placed in plague-infected houses if unprotected from fleas may contract the disease, whereas such animals under the same circumstances remain free from plague if protected from fleas. (*f*) The commission have also performed numerous experiments with a view of testing other possible modes of infection, and have found that—(i.) In the absence of fleas no epidemic resulted when animals susceptible to plague (guinea-pigs) were kept in close contact with infected animals, although the animals took their food off floors grossly contaminated by the excreta of their infected companions; (ii.) that susceptible animals (guinea-pigs) caused to live upon and feed off floors artificially saturated with plague cultures failed to contract the disease; and (iii.) that the excreta of plague-infected patients may contain plague bacilli, but the bedding, &c., of plague patients soiled with excreta containing plague bacilli was not found to be infective to highly susceptible animals caused to live in and upon the bedding. The committee therefore consider that *in the great majority of cases during an epidemic of plague man contracts the disease from plague-infected rats through the agency of plague-infected rat fleas.*

4. *The seasonal recurrence and spread of plague.*—(*a*) The committee have obtained no evidence that under ordinary conditions the plague bacillus survives for more than a few days outside the bodies of men, animals, or fleas. (*b*) In large towns plague may persist throughout the year since a few cases of acute plague in men and rats occur during the non-epidemic plague season. (*c*) In villages there was no satisfactory evidence that such persistence is of other than exceptional occurrence and it seems probable that the recurring annual epidemics in such places are due in most cases to fresh importation of the infection. (*d*) There is no evidence that plague infection is carried for more than short distances by the spontaneous movement of rats. Plague appears to be commonly imported into a fresh locality about the persons of human beings, though the transference of infected rats and fleas in merchandise must be considered. (*e*) In districts which suffer annual epidemics of plague, the rat epidemic, on which the human epidemic depends, occurs during some part of that season when the prevalence of fleas is greatest.

THE MEDICAL PROFESSION AND MUNICIPAL HONOURS.

THE following members of the medical profession have been elected or re-elected to the mayoral chair. Brief notes of their medical and municipal careers are given:—

Faversham.—Mr. S. R. Alexander, M.D. Lond., M.R.C.S. Eng., L.S.A., is an old student of London University and Guy's Hospital. He has been chairman of the governors of the Faversham Grammar School for several years, is a trustee of public charities, a governor of Wreight's and Gibbs's Schools, and represents the University of London on the higher education committee. His election to the mayoral chair is believed to be a unique event in the history of the borough, as he has been previously unconnected with the corporation. As Mayor of Faversham he is a Baron of the Cinque Ports, and as such is commanded to attend the Coronation of the King in Westminster Abbey. He married in 1890 a daughter of the late Mr. Alfred George Schiff.

Hartlepool.—Mr. W. S. Gibb, M.B., C.M. Edin., is an honorary physician to the Hartlepools Hospital.

Montgomery.—Mr. Nicholas Watson Fairles-Humphreys, M.R.C.S. Eng., L.S.A. (re-elected), was born in 1837 and studied medicine at St. Bartholomew's Hospital. In 1885 he was elected alderman for the borough of Montgomery and has been 12 times mayor. He is a justice of the peace for the county of Montgomery, was high sheriff in 1882–83, and has been a county alderman since 1889. His grandfather, Nicholas Fairles, justice of the peace for the county of Durham, was the originator of the lifeboat movement and chairman of the first committee.

Newark.—Mr. F. H. Appleby, M.R.C.S. Eng., L.S.A., J.P. (re-elected), was a student of University College, London, and went to Newark 45 years ago as house surgeon to the hospital. He has since practised in partnership in that town, and is now the *doyen* of the profession in Newark and senior honorary surgeon of the hospital. He has done excellent work as lecturer and examiner to the St. John Ambulance Association, and in recognition of his services was appointed Honorary Associate of the Order of St. John of Jerusalem; last March he was promoted to Knight of Grace of the Order. The Volunteer movement has also commanded his active sympathy. He joined the 4th Notts as surgeon in 1884 and gradually rose to be senior medical officer of the North Midland Brigade, ranking as Brigade-Surgeon-Lieutenant-Colonel. On the formation of the Territorial Forces he was

appointed a military member of the County Association, but has now retired with the rank of Lieutenant-Colonel of the Royal Army Medical Corps, T.F. He has also received the V.D. He has been a member of the town council for 20 years and has done good work on the sanitary committee, of which he is chairman, and also in connexion with the isolation hospital. Eleven years ago he was unanimously called to the office of mayor, which he filled with success. Besides being chairman of the free library committee and the museum committee, Mr. Appleby is connected prominently with several educational undertakings in the borough over which he presides.

Oswestry.—Mr. R. de la Poer Beresford, M.D. Glasg., L.R.C.P., L.R.C.S. Edin., L.R.C.P. Lond., V.D. (re-elected) has served his borough in the capacity of medical officer of health for 43 years, which makes him possibly the senior medical officer of health in England. He is the senior surgeon to the Oswestry Hospital and Dispensary and to the Ellesmere Cottage Hospital, and surgeon to the Cambrian Railway Company. He now holds the rank of Colonel, R.A.M.C., T.F., having received his first commission in the Volunteers in 1887.

Ruthin.—Mr. T. Owen Jones, L.R.C.P., L.R.C.S. Edin., L.F.P.S.G. (re-elected), received his medical education at Anderson's College, Glasgow, and qualified in 1894. He obtained the appointment of medical officer of health of the Ruthin rural district in 1898, when he went to reside in that district. He is deputy medical officer to H.M. Prison, inspector of school children, and lecturer and examiner to the St. John Ambulance Association. For six years he was a member of the Ruthin town council. In 1908, although not then a member of the council, he was unanimously elected mayor, which honour he again received in 1909, and this year for the third time has been unanimously chosen to occupy the mayoral chair.

Saffron Walden.—Mr. J. P. Atkinson, M.D. Glasg., L.R.C.P. Lond., L.R.C.S. Edin., was born in 1838. After serving a term of pupilage with Mr. Little, Mr. Young, and Mr. Adams of Boston, he proceeded to Glasgow University, where he received his medical education, and graduated as M.D. with honours in 1863, having previously passed the examination for the diploma of the Royal College of Surgeons of Edinburgh. In the same year he took the L.R.C.P. Lond. Subsequently he settled at Bampton, Oxon., but removed in 1881 to Saffron Walden, and finally retired from practice in 1908. He entered the town council of the borough of Saffron Walden in 1888 and in 1891 was elected mayor, being re-elected in the following year. He was again appointed in 1900 and re-elected in 1901, and was mayor at the time of the Coronation of the late King Edward VII. and received the Coronation medal. This year he has been elected mayor for the fifth time. Dr. Atkinson joined the medical staff of the 3rd V.B. the Suffolk Regiment, received the V.D. in 1904, and retired with the rank of surgeon-colonel in 1905. He has represented the town council on the joint isolation hospital board, of which he has been chairman since its incorporation in 1903, is a member of the Essex County Territorial Force Association, and has represented the borough on the Essex county council, and also on the county association recently formed for combating consumption.

Warrington.—Mr. G. W. Joseph, M.D. Durh., L.R.C.P.I., M.R.C.S. Eng., L.S.A., is an ex-president of the Warrington Medico-Ethical Society and was lately medical officer of health and public analyst for the borough of Warrington.

Wrexham.—Mr. S. Edwards Jones, L.R.C.P., L.R.C.S. Edin., L.F.P.S.G., who received his medical education at Anderson's and St. Mungo's Colleges, Glasgow, qualified in 1892. He was a prizeman in medicine and operative surgery. After holding the appointment of senior house surgeon at Glasgow Royal Infirmary in 1893–94 he commenced private practice. He has been a member of the Wrexham board of guardians and rural district council since 1905 and takes a keen interest in all public health matters. At one time he was medical officer of health for the combined borough and rural districts of Wrexham. In 1906 he was elected a member of the Wrexham town council and has been chairman of the health committee for three and a half years. In 1909 he was returned to the council without opposition and successfully advocated several important improvement schemes with regard to the health of the borough.

MEDICINE AND THE LAW.

Macrae v. *Harness: The Care of an Infant Mentally Defective.*

Mr. Justice Swinfen Eady was occupied for six days in hearing and deciding in the Chancery Division the claim of Douglas Gordon Macrae, a young man suing through the committee of his estate his step-mother, Mrs. Harness. The action was brought to obtain a declaration that money paid by the lad's trustees to the defendant during the plaintiff's minority for his maintenance and education had not been properly expended upon these objects and for an account of the money thus paid to her. Young Macrae was the son of a wealthy man who died in 1901, leaving the plaintiff, a boy 15 years of age, and a daughter. From the estate of the deceased an income of about £4000 a year was paid to his widow, whom he had married in 1897, and who was expected to keep up the principal residence of the deceased, a country house at Collingbourne. Out of the other half of her husband's estate the trustees allowed this lady £3000 a year in respect of the maintenance and education of her two step-children. The boy, according to her evidence, showed signs of mental weakness during his father's lifetime, giving trouble at home and at two schools which he had had to leave. In 1901, when the father had died, the conclusion was arrived at that the plaintiff's mental condition required special care, and the following provision was proved in the course of the case to have been made for it. At first a house was rented on his account at Eastbourne, where he resided under the care of Mr. H. N. Harness, a medical man who had been called in to attend him in London. Mr. Harness remained in charge until March, 1902, and then left. The patient remained at Eastbourne until December, 1902, the cost of his maintenance there being at the rate of £1200 a year, £50 per month having been paid to Mr. Harness during his care of the case. In December, 1902, Mr. Harness became engaged to Mrs. Macrae, whom he married in the following February. In January, 1903, Mr. Harness had arranged with Dr. Harry Corner that the boy should be taken charge of by him in a private home at New Southgate, the payment to be 4 guineas a week, to include board, lodging, laundry, and medical attendance, and an additional 2 guineas a week for a private attendant to sleep in the patient's room. According to Dr. Corner's evidence, the question of expense was to be considered, and, as a matter of fact, the inclusive charge was eventually reduced to 5 guineas per week, when it was considered that the patient would require less exclusive attention. At one time when £20 extra per month was charged in respect of the necessary employment of extra nurses, Dr. Corner was informed by Mr. Harness that this was more than could be afforded. The lad improved under Dr. Corner's care and was reported to the Commissioners in Lunacy as having no symptoms of insanity. In July, 1904, young Macrae, who had been removed from Dr. Corner's establishment, was placed under the care of a medical man at Farnborough, an arrangement being made for the payment of 6 guineas per week, to include an attendant, not necessarily trained, and not more than £1 for amusement. Evidence was given by this medical man's wife that Mrs. Harness in an interview with her said that she would also pay for anything very necessary or urgent. The limit of £1 a week for amusements was denied by the defence. The expense of a special attendant during a trip to Ireland was refused. The plaintiff remained at Farnborough for 18 months and then went back to his relations, living with them at a house where Mr. Harness did not himself reside, but where he spent his week ends. At a later date the plaintiff was placed in the care of Mr. A. Moore at Pailton Hall, near Rugby, where the provision for him, if proportionate to the payment made for it, was in the opinion of Dr. F. Bryan, who visited him in January, 1908, at the instance of the lunacy authorities, wholly inadequate and unsatisfactory, and where the treatment included the use of mechanical restraint and of drugs, stated to be chloral and hyoscine, in quantities sufficient to be injurious to the patient. One of the attendants employed was a groom or stable helper. The attention of the lunacy authorities had by this time been called to the case, and as a result of the inquiry held by a Master in Lunacy the plaintiff was placed under the care of Dr. Bryan, and since then had improved markedly in health. In the opinion of Dr. Bryan the treatment with drugs

to which the plaintiff had been subjected would have been likely to endanger his life if persevered in. It was stated by Mr. Harness that the treatment given by Mr. Moore, including the drugs used, was according to the recommendation of Dr. Krumbholz, whose instructions Mr. Moore followed. Mr. Moore was not called as a witness, and an application was made to the judge at the close of the evidence that he might be allowed to make a statement in view of what had been said with reference to him. Unfortunately his lordship was not able to permit this, but he referred in his judgment to the hardship of the circumstances in which Mr. Moore was thus placed. It may be observed that with regard to the gentlemen in whose care the plaintiff had been, and who gave evidence, it was not alleged that their treatment was other than proper and in accordance with the amount of the sum paid for the accommodation, board, and attendance arranged for on the plaintiff's behalf. In giving judgment Mr. Justice Swinfen Eady reviewed the evidence, laying stress upon that of Dr. Bryan as to the improvement in the lad's condition under his charge, and it should be stated that the arrangement sanctioned by the court with regard to this allowed the spending of an annual sum of £1700 for the plaintiff's maintenance. In reviewing the negotiations and arrangements entered into by Mr. Harness, his lordship held that it was not a question with him of what should be done in the boy's interest, but of economy. It was clear, he added, from the cross-examination of Mr. Harness, that the relatives of the boy had not been consulted with regard to his removal from Dr. Corner's home, and that a statement made by Mr. Harness in a letter to Dr. Corner to the effect that the relatives were agreed that he must be so removed, because the extra payments of £20 a month could not be afforded, was untrue. "It is quite impossible," his lordship said, "to read Mr. Harness's letters without seeing that the boy's welfare was the last consideration and economy the first." Mrs. Harness's statement that the boy was removed from Dr. Corner's care because Mr. and Mrs. Harness wanted him at home was, in his lordship's opinion, absolutely untrue. He expressed himself as satisfied with the evidence of the medical men with whom the plaintiff had resided, and where their evidence came into conflict with that of Mr. and Mrs. Harness he believed the former and not the latter. After referring in detail to the period spent at the house of Mr. Moore and to the fact that when it was telegraphed to the defendant to Norway that the lad was worse she did not return but only telegraphed back that he should be removed to an asylum, his lordship gave judgment in the plaintiff's favour. The issue to be determined was whether during the time involved he had been maintained in a reasonable and proper manner having regard to his position and means. His lordship was of the opinion that he had not been so maintained, and that Mrs. Harness had failed to discharge her duty as his guardian. He said a declaration would be granted to that effect, and also a declaration that the defendant was liable to account for £18,847 paid to her by the trustees between April, 1901, and August, 1907, when the plaintiff came of age, proper deductions to be made in respect of expenditure upon the education and maintenance of the plaintiff and his sister. The costs of the action he ordered to be paid by the defendant.

LITERARY INTELLIGENCE.—Mr. H. K. Lewis will publish almost immediately a new work dealing with the new organic arsenic compound "Diamino-dioxy-arseno-benzol," the famous "606," which is intended to provide in a handy and condensed form information not readily accessible elsewhere. Recent English and foreign literature on the subject is given. The writers are Mr. W. H. Martindale and Dr. W. Wynn Westcott, the well-known authors of the "Extra Pharmacopœia." The same firm has also just ready a monograph on "Meningitis, Sinus Thrombosis and Abscess of the Brain," by Dr. John Wyllie, author of "Tumours of the Cerebellum." The work contains appendices on Lumbar Puncture and Diseases of the Nasal Accessory Sinuses.—Messrs. Baillière, Tindall, and Cox inform us that they hope to publish early next year an English edition of Brünings's "Direkte Laryngoskopie," with some additional matter, bringing it right up to date, supplied by the author.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Nottingham.—Dr. Philip Boobbyer deals in his current annual report with the sanitary circumstances of a population of 263,441, the general death-rate of which for 1909 was 16·20 per 1000, while the birth-rate was 25·6 per 1000; the infantile mortality figure amounted to 150 per 1000 births. There has been a marked fall in the percentage of children successfully vaccinated within recent years, and in the first half of 1909 there were no fewer than 1728 certificates of exemption obtained as compared with 829 in the previous half year. As to any administrative methods Dr. Boobbyer observes that "conscientious objection as interpreted by the average objector is not only broadly farcical in itself but is rapidly reducing compulsory vaccination to something of the same order," and he adds that the gratuitous statutory provision for escaping vaccination is so simple that it is regarded by many persons as an authoritative encouragement to evade vaccination, a statement which is, in our opinion, quite a moderate one. Commenting upon the employment of diphtheria antitoxin Dr. Boobbyer refers to the large number of cases of diphtheria in which the use of this absolutely essential treatment has been neglected, and he states that cases are frequently sent into hospital which have received no serum, although the disease has been diagnosed for several days, and this notwithstanding the fact that the antitoxin is distributed gratuitously for the use of poor patients. The death-rate from enteric fever was 7 per 100,000, as compared with a rate of 3 for London and 6 in England and Wales generally. As is well known, Dr. Boobbyer attributes the excessive enteric fever death-rate of Nottingham largely to the persistence of the conservancy system of excrement disposal, and his annual reports for several years past contain some very instructive data upon this subject, as well as with reference to a high diarrhœa mortality, which is also attributed largely to the retention of the pail system. Writing upon the subject of tuberculosis, attention is directed to the provision in the grounds of the isolation hospital at Bagthorpe which is intended partly as an educational establishment and partly as a hospital. During 1909 the average stay of the patients was a little under three months, the weekly charge being 10*s.* 6*d.* One of the most interesting features in connexion with the Bagthorpe Hospital is the practice which has now obtained for some years of nursing cases of acute specific disease as far as practicable in the open air. Experience shows, Dr. Boobbyer is confident, that cases thus dealt with do better than in the ordinary wards and no untoward results have accrued. As regards what is known as the "barrier" system of treating cases of infectious disease—that is to say, the isolation or insulation of each patient's bed in a space by itself by means of a screen, cord, or tape—Dr. Boobbyer thinks that it is an excellent precaution against contact, which he regards as the principal means of infection, and as a method of impressing upon nurses and others the full meaning of physical isolation. He thinks, however, that the system is very difficult to carry out in its entirety with young patients of the poorer classes and with a limited nursing staff. In his opinion the open-air treatment above referred to is preferable, so much so that he is advocating the alteration of all the ward blocks so as to afford facilities for such treatment—i.e., the provision of an open verandah extending along the entire side of each ward block and communicating with the wards by French casement windows extending to the floor. The advantage of hospital accommodation for patients suffering from enteric fever is emphasised by Dr. Boobbyer, and we quite agree with him that it is rarely possible to properly nurse at home patients suffering from this disease. The Notification of Births Act, 1907, has been in force in Nottingham since May, 1908, and during 1909 there were 4900, or 73 per cent. of all the births registered, notified. It is, of course, provided by the Act that all births shall be notified, but the number above given includes all thosein which useful action can be taken by the sanitary authority. The number of certified midwives amounted in 1909 to 86, and of these 50 per cent. were engaged in active practice.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7347 births and 5617 deaths were registered during the week ending Nov. 26th. The annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 13·0 to 15·5 per 1000, further rose to 17·3 in the week under notice. During the first eight weeks of the current quarter the death-rate in these towns averaged 14·1 per 1000. In London the death-rate during the same period, calculated on the probably over-estimated population, was equal to 14·4 per 1000. Among the 77 towns the death-rates last week ranged from 7·8 in Wallasey, 9·0 in Hornsey, 9·2 in King's Norton, and 9·6 in West Hartlepool, to 23·8 in Stoke-on-Trent, 24·8 in Huddersfield, 26·3 in Middlesbrough, and 26·8 in Tynemouth. The 5617 deaths from all causes in the 77 towns last week showed a further increase of 577 on the numbers in recent weeks, and included 420 which were referred to the principal epidemic diseases, against 361, 392, and 403 in the three preceding weeks; of these 420 deaths, 192 resulted from measles, 67 from diarrhœa, 56 from whooping-cough, 54 from diphtheria, 26 from scarlet fever, and 25 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·3 per 1000, against 1·2 in each of the two preceding weeks. No death from any of these diseases was registered last week in East Ham, Walthamstow, South Shields, Preston, Hornsey, or St. Helens; the annual death-rates therefrom ranged upwards, however, to 3·9 in Rotherham, 4·7 in Tottenham, 5·4 in Plymouth, and 5·5 in Tynemouth. The fatal cases of measles in the 77 towns, which had been 101, 136, and 164 in the three preceding weeks, further rose last week to 192, and exceeded the number in any previous week of this year; they caused the highest annual rates, 2·3 in Brighton, 3·5 in Tottenham, 4·6 in Tynemouth, and 5·4 in Plymouth. The deaths attributed to diarrhœa, which had declined in the 12 preceding weeks from 527 to 75, further fell last week to 65, and were proportionally most numerous in Walsall. The deaths referred to diphtheria, which had been 54 and 55 in the two previous weeks, were again 54 last week; they included 16 in London and its suburban districts, 6 in Manchester and Salford, and 3 each in Swansea, Stoke-on-Trent, and Liverpool. The 56 fatal cases of whooping-cough showed a slight further increase upon recent weekly numbers, and caused annual rates equal to 1·2 in Norwich and 1·6 in Rotherham. The 26 deaths from scarlet fever were fewer by 7 than the number in the previous week; 3 occurred in Bury and 2 in Stoke-on-Trent. The deaths referred to enteric fever, which had been 32 and 21 in the two previous weeks, rose again last week to 25; they included 3 in Wigan, 3 in Manchester, and 2 each in Stoke-on-Trent and Blackburn. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had been 1882 and 1843 at the end of the two preceding weeks, had further declined to 1769 on Saturday last; 153 new cases of this disease were admitted to these hospitals during last week, against 239 and 180 in the two previous weeks. The 1810 deaths from all causes in London last week included 558 which were referred to pneumonia and other diseases of the respiratory system, against 246, 319, and 396 in the three preceding weeks, and exceeded by 185 the corrected average number in the corresponding week of the five years 1905–09. The causes of 48, or 0·9 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified last week in Leeds, West Ham, Bradford, Newcastle-on-Tyne, and in 49 other smaller towns; the 48 uncertified causes of death in the 77 towns last week included 6 in Birmingham, 5 in Liverpool, 5 in Gateshead, and 3 each in St. Helen's, Manchester, Rochdale, and South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 834 births and 600 deaths were registered during the week ending Nov. 26th. The annual rate of mortality in these towns, which had been equal to 13·3 and 16·2 per 1000 in the two preceding weeks, further rose to 16·5 in the week under notice. During the first eight weeks of the current quarter the death-rate in these eight towns averaged 14·1 per 1000, and corresponded with the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 10·8 and 12·4 in Leith and Aberdeen, to 22·9 in Paisley and 26·6 in Perth. The 600 deaths from all causes in the eight towns last week showed a further increase of 12 upon the numbers in the two previous weeks, and included 55 which were referred to the principal epidemic diseases, against 47 and 61 in the two preceding weeks; of these 55 deaths, 15 resulted from diarrhœa, 14 from diphtheria, 12 from whooping-cough, 11 from scarlet fever, 2 from "fever," and 1 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·5 per 1000, and exceeded by 0·2 the rate from the same diseases in the 77 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had been 17 and 24 in the two previous weeks, declined to 15 last week, of which 9 occurred in Glasgow and 2 both in Edinburgh and Greenock. The 14 fatal cases of diphtheria showed an increase of 6 upon the number in the previous week, and included 5 in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The 12 deaths from whooping-cough were within 1 of the number in the previous week; 8 were returned in Glasgow. The fatal cases of scarlet fever, which had been 6, 7, and 5 in the three preceding weeks, rose to 11 last week, of which 6 occurred in Glasgow and 4 in Dundee. The 2 deaths referred to "fever" and the fatal cases [of measles were recorded in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had been 65 and 121 in the two preceding weeks, further rose last week to 138, but were 160 below the number in the corresponding week of last year. The causes of 16, or 2·7 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 529 births and 423 deaths were registered during the week ending Nov. 26th. The mean annual rate of mortality in these towns, which had been equal to 15·1, 16·2, and 17·9 per 1000 in the three preceding weeks, further rose to 19·1 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these Irish towns averaged 16·9 per 1000; the mean rate during the same period did not exceed 14·1 in the 77 largest English towns or 14·4 in the eight Scotch towns. The annual death-rate during last week was equal to 21·0 in Dublin, 17·9 in Belfast, 17·1 in Cork, 16·8 in Londonderry, 5·5 in Limerick, and 11·7 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 24·1 per 1000. The 423 deaths from all causes in the 22 town districts last week showed a further increase of 27 upon the numbers in recent weeks, and included 29 which were referred to the principal epidemic diseases, against 27 and 18 in the two previous weeks; these 29 deaths were equal to an annual rate of 1·3 per 1000, corresponding with the mean rate from the same diseases last week in the 77 English towns, the rate in the eight Scotch towns being 1·5. The 29 deaths from these epidemic diseases in the Irish towns last week included 9 from whooping-cough, 8 from measles, 6 from diarrhœa, 3 from diphtheria, 2 from enteric fever, and 1 from scarlet fever, but not one from small-pox. The 8 fatal cases of measles showed a marked increase, and included 5 in Lurgan and 2 in Belfast. The 9 deaths from whooping-cough also showed an increase upon the numbers in recent weeks; 6 were recorded in Dublin. The 6 deaths attributed to diarrhœa, including 4 in Dublin, corresponded with the number in the previous week. Two of the 3 fatal cases of diphtheria and both the deaths referred to enteric fever were returned in Dublin. The death from scarlet fever occurred in Belfast. The deaths in the 22 towns last week included 100 which were referred to pneumonia and other diseases of the respiratory system, against 88 and 80 in the two preceding

weeks. The causes of 12, or 2·8 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·9 per cent., and in the eight Scotch towns it was equal to 2·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet (dated Nov. 21st, 1910):—Michael Joseph Laffan, Archibald Denizé Spalding, Alexander McCloy, Thomas Aubrey Smyth, Frederick Eustace Anley, Arthur Davidson, and Gerald Coneybeare Cross.

In accordance with the provisions of Order in Council of April 1st, 1881, the undermentioned officers have been placed on the Retired List:—Fleet-Surgeon Alfred Matthew Page, Surgeon William Hutcheson (dated Nov. 10th, 1910).

In accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Horace Ximenes Browne has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Nov. 24th, 1910).

Acting Surgeon Robert Nicholas William Walter Biddulph has been confirmed in the rank of Surgeon in His Majesty's Fleet (dated May 6th, 1910).

In accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon George Alexander Stuart Bell has been placed on the Retired List at his own request (dated Nov. 29th, 1910).

ROYAL ARMY MEDICAL CORPS.

Colonel J. C. Culling, late senior medical officer at Bermuda, has taken over the appointment of Principal Medical Officer of the Western Command in succession to Colonel R. Porter, appointed Principal Medical Officer at Malta. Lieutenant-Colonel P. C. H. Gordon has been appointed to the charge of the Military Hospital and Senior Medical Officer of the Coast Defences at Pembroke Dock. Lieutenant-Colonel H. N. Thompson, D.S.O., commanding the Station Hospital at Lucknow, has been selected for increased rate of pay under Article 317 of the Royal Warrant. Major T. B. Beach has taken over duty in Egypt from the Aldershot Command. Major F. R. Buswell has left the London District for a tour of foreign service in India. The following officers have been appointed to the Irish Command for duty:—Captain R. C. Hallowes and Captain J. S. Pascoe from Cairo, Captain H. E. Gotelee from Ceylon, and Captain P. A. Lloyd Jones from Malta. Captain A. F. Carlyon, on the termination of his tour of service on the West Coast of Africa, has been posted to the Southern Command. Captain F. C. Lambert, from Wool Camp, has taken up duty at Cosham. Captain D. P. Johnstone has been transferred from Brackenbir Moor to Liverpool. Captain R. G. A. Tate has been appointed to the charge of the Sirhind Brigade Laboratory at Ambala. Captain W. M. B. Sparkes has joined for duty in Ireland, and has been posted to the Dublin District. Lieutenant A. T. J. McCreery, from Tidworth Park, has been posted to West Down North. Lieutenant S. McK. Saunders, from Woolwich, has embarked for a tour of foreign service in Egypt. Lieutenant W. E. Marshall has arrived home on leave from Egypt.

INDIAN MEDICAL SERVICE.

The Lieutenant-Governor of Burma has appointed Colonel H. St. Clair Carruthers, Officiating Inspector-General of Civil Hospitals, to be a Member of the Educational Syndicate in Burma in succession to Colonel W. G. King, C.I.E., who has resigned his appointment. Lieutenant-Colonel W. H. E. Woodwright, civil surgeon of Bareilly, has been appointed Medical Officer of the Central Prison at Bareilly during the absence on leave of Major C. B. Prall. Lieutenant-Colonel C. E. L. Gilbert has been granted eight months' leave home from India on medical certificate. Major J. Fisher, on return from leave, has been appointed under the Foreign Department of the Government of India to be Residency Surgeon at Jaipur in succession to Lieutenant-Colonel W. H. B. Robinson. Captain G. A. Jolly and Captain A. E. Roberts have arrived home on leave from India. Captain T. T. Owen, whose services hav been placed at the disposal of the Burma Government, has been appointed to officiate as Chemical Examiner and Bacteriologist at Rangoon, relieving Major F. N. Windsor, whose services have been replaced at the disposal of the Government of India. Captain A. H. Burgess has received three months' extension of his leave home from India. Captain H. R. Dutton has been appointed Civil Surgeon at Purnea. The services of Captain A. C. MacGilchrist have been replaced at the disposal of the Bengal Government. Captain W. H. Boalth has been appointed to the Substantive Medical Charge of the 104th Wellesley's Rifles. Captain F. N. White, on special duty under the Sanitary Commissioner with the Government of India, has been granted eight months' combined leave. Lieutenant G. G. Jolly has been appointed Specialist in Radiography and Electrical Science to the Fourth (Quetta) Division of the Southern Army.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Bertram C. A. Leeper resigns his commission (dated Nov. 26th, 1910).

Attached to Units other than Medical Units.—Lieutenant William E. F. Tinley to be Captain (dated Oct. 1st, 1910). Major Andrew P. Arnold resigns his commission (dated Nov. 26th, 1910). Lieutenant Frank M. Bingham resigns his commission (dated Nov. 26th, 1910).

For attachment to Units other than Medical Units.—Arthur Henry Falkner, late Lieutenant, 5th Battalion, The King's Own (Royal Lancaster Regiment), to be Lieutenant (dated Nov. 26th, 1910).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain Harry Armitage Robinson, from the Territorial Royal Army Medical Corps, to be Captain, with precedence as in the Territorial Force (dated Nov. 26th, 1910).

MEDICAL OFFICERS' SICK LEAVE.

The terms of Article 167 of the Pay Warrant, which prescribes that the sick leave up to 30 days which can be deducted from the calculation of the 61 days' leave allowed by Article 162, must only be in respect of the illness of an officer while actually at his station, have been modified subject to the condition that the employment of paid substitutes to any greater extent than is now contemplated must be avoided. General officers commanding will be at liberty to permit sick leave at whatever place the officer may be under treatment up to 30 days, if duly certified by a medical officer, not to count against the normal 61 days.

ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.—A meeting of the council of the above association was held on Nov. 24th. Mrs. Samuel Bruce, who kindly lent her house for the occasion, occupied the chair. Mrs. Wallace Bruce, chairman of the executive committee, gave a short account of the work of the association during the year, and referred in particular to the Midwives (No. 2) Bill. She said there were two points upon which the executive committee of the association felt strongly—viz., Clause 12 (1) (*b*), which would permit a midwife qualified under regulations of the Local Government Board for Ireland to be entitled to be certified under the principal Act and to practise in England; and Clause 17, relating to the payment of doctors' fees. In the first case the committee considered that the clause should be omitted entirely, as it did not deal in any way with the regulation of midwives' practice in Ireland, for which a separate Bill was necessary, while it would allow a second standard of qualification for midwives practising in this country—a suggestion greatly deprecated by the association, as well as by a large majority of those who gave evidence on this point before the Departmental Committee in 1909. Miss Lucy Robinson gave an account of the training given under the auspices of the association and of the Training Home at East Ham. Miss Lorent Grant made a financial statement, and Mr. F. E. Fremantle, in a short speech, asked the members of the association to bear in mind that they wanted the Bill to pass without serious delay, and not be made a pivot or test question of Poor-law reform, but to be considered on its own merits. In conclusion, Lady St. Davids gave an address on the Organisation of District Nursing in South Wales.

"Audi alteram partem."

THE QUALIFICATIONS FOR HOSPITAL APPOINTMENTS.

To the Editor of THE LANCET.

SIR,—It surely is an anomalous, if not paradoxical, position in hospital ethics that in connexion with two London hospitals advertisements should contemporaneously appear containing these conditions for candidates for positions on their staffs. The West London Hospital advertises for a physician who must be a Member of the Royal College of Physicians of London, though a member of the surgical staff may be a Fellow of the Irish or Scotch colleges. On the other hand, at West Ham the reverse of this holds good; the obligation does not apply to the medical, but only to the surgical staff. That is to say, the qualification which is good enough for the one in surgery is rejected by the other, and that that in medicine which is accepted by one hospital is ignored by the other.

At the recent dinner of the Irish Medical Schools and Graduates' Association Sir Alfred Keogh, ex-Director-General, A.M.S., spoke strongly on the absurdity of this anomaly, and an object-lesson was afforded on the same occasion, when among other distinguished Irish graduates and diplomates present were the Director-General of the Army Medical Department, the ex-Director-General, and Sir Thomas Gallwey, at present holding the chief command at Aldershot. It is not so long since the post of commandant at Netley Hospital was held by a distinguished Irishman, Sir Edmond Townsend, and successive principal medical officers in Egypt have been Irish graduates.

Anyone not in the secret as to the motives which animate hospital boards of management may be excused if in his ignorance he does not quite understand why the lives of His Majesty's sailors and soldiers are of less importance than the patients in public institutions in this country, or, to go even further than this, that His Majesty himself should be rash enough to trust his royal person during his tour throughout India, as Prince of Wales, to the custody of an Irish graduate, now one of his medical advisers—Sir Havelock Charles. Again, one is at a loss to explain how the present Governor-General of India has had all through his Viceroyalty another Irish graduate as his personal adviser.

I address this letter to THE LANCET, inasmuch as it has always taken a broad and liberal view on this question. It is to be hoped that the time is not far distant when an end will be put to such exclusiveness through the advent of a State licence which will entitle the holder to become a candidate for any public appointment in the United Kingdom.

I am, Sir, yours faithfully,

AN EX-PRESIDENT OF THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

London, Nov. 29th, 1910.

WHO IS HE?

To the Editor of THE LANCET.

SIR,—The excellent photograph which appeared under the above heading in Dr. Thomas Bushby's letter in THE LANCET of Nov. 26th enabled me at once to identify it as that of the bust of Thomas Waterhouse, which stands in the library of the Sheffield Medico-Chirurgical Society at the University of Sheffield. A short account of his life is given by the late Simeon Snell in the century history of the Sheffield Royal Infirmary,[1] from which I extract the following facts:—

Thomas Waterhouse was born in 1793, and commenced practice as a surgeon in 1816 at Sheffield. In 1820 he was elected one of the honorary surgeons to the infirmary. He took considerable interest in the establishment of the Medical School in 1828, and contributed £110 to the building fund. He also presented to the school his excellent collection of specimens of morbid anatomy, as well as books, &c. The late Sir James Risdon Bennett was at one time his pupil. He was also the senior of the two first honorary secretaries of the Sheffield Literary and Philosophical Society, founded in 1822 and still flourishing. He died of aneurysm of the aorta on April 8th, 1830, after having been previously operated on for aneurysms of both femoral arteries, by his friend, Mr. Hodgson of Birmingham. "Thus," says Snell, "a life of considerable promise was cut short at the early age of 36."

The following paragraph is copied from the eighth annual report of the Sheffield Literary and Philosophical Society, presented January, 1831:—

> The committee cannot omit to allude to the heavy loss sustained by the society in the death of one of its vice-presidents. The late Mr. Thomas Waterhouse had not only proved a valuable supporter of the institute in the several capacities of secretary, member of council, and contributor of papers, but is entitled to especial and honourable mention in this place as one of the founders of the society, who zealously took up the cause, when many were lukewarm or desponding, and perseveringly coöperated with heart and hands in its first establishment and subsequent proceedings.

It is of interest to add that the bust was executed in 1831 by the able young sculptor, Edward Law, brother of Dr. Joseph Law, who was for many years physician to both the General Infirmary and the Public Hospital and Dispensary, Sheffield, and whose portrait now hangs in close proximity to the marble bust of Thomas Waterhouse.

I am, Sir, yours faithfully,

R. J. PYE-SMITH,
Treasurer to the Sheffield Medico-Chirurgical Society.

Nov. 28th, 1910.

THE MIAN MIR EXPERIMENTS.

To the Editor of THE LANCET.

SIR,—In your leading article of Oct. 26th dealing with a report by the committee appointed by the Government of India to inquire into results obtained by anti-malarial experiments at Mian Mir, you note that the subject has been one of controversy. That this is so is due to the fact that, under the influence of reputed failure in that locality of methods held to be of utility in other parts of the world, the Government of India has failed to make its local governments understand that the regarding of anti-malarial measures seriously would have its approval; and it goes without saying that in the absence of such declaration of policy no local government would consider itself safe in directing any appreciable part of its own funds, or those of local bodies under it, to this end. Hence there has occurred a paresis of efforts in a country which should, in the natural course of events, have been the first to reap the benefit of Ross's discovery. This condition of affairs has been received by the profession with yearly increasing surprise. The appointment of the committee was therefore a convenience of the usual official type—permitting of justification or, in its absence, the securing of the possibility of strategic retreat. The enquiry implied the entering into so great a mass of petty details that to have managed to inspect Mian Mir, examine witnesses, travel to and from Simla, and compile the report, in the short time allowed, must have left the committee little time to consider its conclusions; and it is certainly here that the weak point of its labours is evident.

In the face of knowledge that mosquito-reduction methods have elsewhere proved successful, and being of opinion that little if any results had been secured at Mian Mir, the committee has marshalled the local physical conditions as presenting unusual difficulties, and as all-sufficient reasons why success had not been attained. It has apparently assumed as unquestionable that efforts which it testifies to as energetic were also discreet and were correctly carried out; but seeing that these experiments were specifically of the nature of a test of the utility or inutility of methods which deeply concern the sanitary and economical condition of over 230,000,000 of the people of India, it would have been reasonable for the committee to have established their correctness. Hence, from the facts as recorded by the committee and experimenting officers respectively, I would invite attention to this aspect of the matter, as affording a simple solution of the differences of opinion which have arisen on this subject.

The experiments were inaugurated by the Royal Society in 1901 "to demonstrate the reduction of malaria in a cantonment by measures based upon the recent etiology of this disease." The officers of the expedition were Dr. Stephens

[1] Sheffield General Infirmary, now the Sheffield Royal Infirmary, 1797–1897: a Brief Sketch of a Century's Work, by John Daniel Leader, F.S.A., together with Reminiscences and Biographical Notices of the Medical Staff, by Simeon Snell, F.R.C.S. Ed. Sheffield, 1897.

and (then) Mr. Christophers. Preliminary investigations by these officers occupied about six months. On their departure to England, Major James, I.M.S., was deputed by the Government of India to carry out the anti-malarial operations, and was in charge of this work from April, 1902, to July, 1903. He elected to follow certain dicta of Professor Ross, as gathered from his speeches and publications as to the advantage of "mosquito reduction." The quotations thus relied upon (pp. 6 and 7 of the Report) discuss applicability of methods, not in special, but in general, cases. The most definite of the quotations is as follows:—

> It is now a matter of the general experience of many investigators that where mosquitoes abound in a house, their larvæ can easily be found at a short distance, within a few hundred yards of the house. Occasionally, where the house is isolated, and no stagnant water is in its immediate vicinity, mosquitoes may attack it from a greater distance; but this is exceptional, and in the great majority of cases, especially in towns, almost every house breeds its own mosquitoes in its backyard, or in puddles or in drains in the streets close by.

Now the average mortal would think before making a *test* experiment that would take several months to work out, based on a statement of this general nature, the first step would be to ask the authority making it to define, as precisely as feasible, what is meant by "a few hundred yards" or "greater distance." No reference was, however, made to Professor Ross on the subject. Failing this mode of arriving at a basis, at least an independent determination of distance should have been arrived at, and, whatever that might be, in applying it to the area selected for operations it should have been observed without variation from the most external inhabited house of the groups of dwellings to be protected. In aid of arrival at this decision there were several records of observations in pre-Ross days as to distances of the "diffusion of malaria" that, by substitution of the mosquito for air, should at least have dictated caution. Indeed, in the year preceding these experiments, Celli had drawn attention in his book then published to observations by Ambrosi and Riva on this subject. Moreover, *previous* to inauguration of the Mian Mir operations, Stephens and Christophers, working in the Central Provinces, had arrived at the conclusion that the distance of a quarter of a mile was commonly, and half a mile was exceptionally, the flight of certain anopheles. Yet in attempting to explain his psychological attitude towards the Mian Mir controversy, his preference for quinine prophylaxis, and consequent absence of adequate anti-malarial measures in India, the Sanitary Commissioner with the Government of India, at p. 98 of his report for 1908, whilst placing stress upon the "few hundred yards" phrase and carefully ignoring the suggestion of "greater distance," would incorrectly desire it to be understood that this observation was not available for guidance in April, 1902, or July, 1903. But Major James, putting all such considerations aside, was content to select an area for mosquito reduction operations which itself had not equal sides ("one mile north and south and rather over ¾ mile east and west"), and the treated area round the habitations of which also was not equal. His limit, according to the committee, was drawn "close round the residential quarters, no attempt being made to deal with outlying uninhabited areas." Reference to the committee's map shows that this line abruptly excluded numerous pits and rain-fed depressions; and it becomes necessary to believe that whilst on the west he considered 40 yards of treated area would suffice for the protection of external dwellings, 200 and 260 yards were requisite on the east. The position of pits and rain-fed depressions, as shown on the map and described by the committee as still existing, certainly would not justify this differential treatment. Within this dubious area he proceeded to effect "mosquito reduction" operations—that is, by the abolition of pools, or by the making of them unfit by petrolage for breeding by mosquitoes in the "immediate vicinity" of houses (the prime point of danger as insisted by Ross), he brought about a condition equivalent to "no stagnant water" in the vicinity, well knowing that within a "few hundred yards" or "greater distance" there existed pools which might favour invasion from a distance. He therefore conspicuously failed to take due cognisance of the dicta which it is professed afforded him guidance. It is remarkable in contrast that Dr. Balfour,[1] in his excellent work at Khartoum, which has recently been eulogised by Lord Kitchener, found no similar difficulty in following Ross's meaning. Captain Christophers having returned from Europe in the Indian Medical Service, relieved Major James of duty at Mian Mir in July, 1903. He describes the area selected by Major James as "to a large extent isolated from the rest of the cantonment." Yet he held that a bazaar, 400 yards from the barracks within the protected portions, was an infective centre. As he held this opinion, it is difficult to understand the rigidity with which he excluded the Native Cavalry Lines and the East Infantry Lines which were within an additional 100 yards—that is, a total of 500 yards—of the most external of the dwellings to be protected. At the end of August he found that mosquitoes might invade from a distance of three-quarters of a mile, and then determined to enlarge Major James's area by three-quarters of a mile "in every direction." This would have been a logical sequence; but some error occurred in his measurements, as the text of his account of his labours, and a comparison of his map[2]—allowing for difference of scale—with that supplied by the committee, show that had such extension been carried out to the north, west, and east, not only would the lines mentioned have been included but the West Infantry Lines also. Both within and without these lines the possible breeding places for mosquitoes were very numerous, as shown by witnesses examined by the committee; and, indeed, up to date these have not been completely got rid of under Surgeon-General Hamilton's scheme. As a result, therefore, even the pools recognised by Captain Christophers as offering danger of invasion were not treated until the three months of the "fever season" (September, October, November) were actually at hand—a state of affairs that would not have precluded adult mosquitoes having already taken up their abode, with ample nourishment at disposal, within the various houses. Again, therefore, there was an absence of fixed ideas of procedure to be followed, or at least uniformity in method; and although doubtless interesting facts as to mosquito biology were gathered, the experiment was useless for the sanitary end originally desired by the Royal Society as defined above. Indeed, the methods were so lacking in uniformity that it is reasonable to believe that of the experimenting officers at least Major James (who was responsible for the inauguration and the longer conduct of the operations) was of opinion that Ross had pledged himself to the statement that, provided larvæ "close" to dwellings (again distances being undefined) were destroyed, no further precaution was required. It is, however, obvious that Ross made no such statement; and it extraordinary that, during the years of inaction which have followed these experiments, this simple fact has been lost sight of by a Sanitary Commissioner predisposed to "quinine prophylaxis"—a method which the committee frankly states "has not hitherto come within the range of practical politics." It is satisfactory to find that the committee whilst providing for those responsible for these experiments a strategic retreat, by adducing the physical conditions at Mian Mir as sufficing to account for the indifferent results secured, shows no disposition to deprecate "mosquito reduction" methods *per se;* on the opposite, it considers their addition to the present quinine prophylaxis policy would offer "great possibilities."

I am, Sir, yours faithfully,

W. G. KING, Colonel, I.M.S. (retired).

ACUTE MYELITIS AND ACUTE POLIOMYELITIS.

To the Editor of THE LANCET.

SIR,—With much of the article by Dr. Bastian on Thrombotic Softening of the Spinal Cord as a Cause of So-called "Acute Myelitis[1]" most observers will be in entire agreement, and in support of the view expressed I may mention the recent article on Acute Myelitis in Clifford Allbutt's "System of Medicine," Vol. VII., p. 645, 1910. With regard to acute poliomyelitis, however, I am afraid I cannot now agree with Dr. Bastian's view. All the recent work of Landsteiner, Popper, Levaditi, Flexner, and Lewis points to the fact that poliomyelitis is an infective disease giving rise to a lymphocytic infiltration of the tissues and walls of the vessels of the spinal cord. This perivascular exudation, though it may fall with special incidence on one portion of

[1] THE LANCET, Nov. 26th, 1910, p. 1531.

the cord, is not limited to a single area, but is of wide distribution. That this perivascular exudation may be so great as to give rise to obliteration of a vessel with the subsequent necrosis of the tissue, no one will deny. Having regard to recent epidemiological and experimental investigation, poliomyelitis must be considered as an infective process. I am perfectly prepared to admit that the evidence brought forward with regard to poliomyelitis during the past years has made me change the view I expressed in the article written in 1904, from which Dr. Bastian quotes.

I consider it most important that poliomyelitis, and with that I include encephalitis, should be regarded as an infective disease, and treated as such. I hope that the time when it will be made notifiable is not far distant, for it will only be by such means that we shall be able to eliminate from the community a disease which in its effects is so disastrous to the usefulness and happiness of many lives.

I am, Sir, yours faithfully,

Harley-street, Nov. 28th, 1910. FREDERICK E. BATTEN.

ULCERATING GRANULOMA OF THE PUDENDA A PROTOZOAL DISEASE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 15th, there is an interesting article by Captain R. Markham Carter, I.M.S., on this subject. He describes as protozoa the bodies found in such cases by Donovan in Madras, as will be seen on comparing his descriptions and drawings with those published in the fourth edition (1907) of Manson's "Tropical Diseases."

It is of considerable importance that a careful search for Donovan's parasites should be made in the places in South America and the West Indies where the disease—misnamed "ulcerating granuloma"—is prevalent, as proof is required of the identity of the diseases so described in different parts of the world. In preserved material from British Guiana I have not been able to find these bodies.

I am, Sir, yours faithfully,

Welbeck-street, W., Nov. 28th, 1910. C. W. DANIELS.

FRACTURES IN THE NEIGHBOURHOOD OF JOINTS.

To the Editor of THE LANCET.

SIR,—As a simple surgeon in a colliery district I beg to express my thanks to Mr. Robert Jones for his timely paper on Fractures near Joints, and my obligation to THE LANCET for putting it within my reach. Surgery has recently made such strides and introduced such innovations that the general practitioner can only await their trial and sentence by those whose position and experience entitle them to pronounce definite opinions upon which he can securely work.

In the first place the scaphoid fractures interested me, as my "paternal Erichsen" and my more modern acquaintance, "Rose and Carless," left me to find my own courses here; and the method of reduction of Colles's fracture by a specialist is useful and important knowledge. The treatment of shoulder and elbow injuries is much at variance with old-established practice, but it appears to be thoroughly rational if empirical, and an increased range of aseptic surgery warrants an increased range of treatment. The importance of massage and the proper time for using passive movement required more definite directions *ex cathedrâ*—the way Mr. Jones "saved the situation" for Drs. A and B deserves all commendation.

The frequency and importance of fractures in children about the hip is fortunately and carefully dwelt upon. Who of us has not on sundry occasions made his second examination in trepidation? Again, the change in method of treating fractures at the lower end of the femur is very marked and, verified by experience, cannot be too strongly urged on those in, or going into, practice, whilst injuries in the neighbourhood of the ankle-joint have to be confronted often, and it is well to bear in mind the possibilities with regard to their occurrence and consequence.

In conclusion, I for one thank Mr. Jones for his lucid and comprehensive paper and for the interest and help I have gathered from it.

I am, Sir, yours faithfully,

Blackrod, Nov. 23rd, 1910. J. GOOD, M.R.C.S Eng.

MALINGERING IN THE ARMY.

To the Editor of THE LANCET.

SIR,—I observe in THE LANCET of Nov. 26th that a paper was read at the meeting of the United Services Medical Society by Major C. E. Pollock, R.A.M.C., on the above subject, and possibly it may be of interest if I mention some actual experiences of my own in this respect. It was in the year 1897, in July as far as I remember, when in charge of the Station Hospital at Up Park Camp, Jamaica. On going the round of the wards for the first time there were five cases under observation for epilepsy, all among negro soldiers of the West India Regiment. It immediately struck me as an unusual number, and to the young medical officer in immediate charge of the cases I expressed my doubts, but he assured me that he was quite certain of three of the number. A few days after, as I was seeing the morning sick, I heard a great commotion in one of the wards, and on proceeding there found one of the three on the floor in one of his fits. Careful observation convinced me it was not genuine, and I so reported to the senior medical officer. He instructed me to act accordingly, so after observing all the cases for a fortnight I discharged to duty the one I had actually seen in the fit.

A few days after, whilst at lunch at the mess, an urgent message was delivered to me to the effect that a prisoner at the cells was in a fit. I went over to the cells at once and there saw the man I had discharged lying on his cot in a fit. Feeling sure of my ground, I asked the sergeant to get me a little cayenne pepper. He brought me a handful, but I selected two or three particles only and placed them on the lower palpebral conjunctiva of the eye nearest to me. The effect was electric, and though apparently quite insensible the man jumped out of bed with the expression, "My King!" Before leaving I told him I would be on duty for the week, and that I could always cure his fits in that way. Next day I promptly discharged the other four. There was no more epilepsy during the time I remained at Up Park Camp; at least no epidemics of the spurious kind.

We discovered afterwards that these soldiers had been attending a sort of school of instruction at Kingston. The school not paying, broke up, and there was an end of the matter.

I am, Sir, yours faithfully,

J. D. RECKITT, M.D., M.R.C.S., L.S.A., &c.,
Lieutenant-Colonel, R.A.M.C. (Ret.).

London, Nov. 28th, 1910.

THE ORIGIN OF THE SOCIETY OF APOTHECARIES.

To the Editor of THE LANCET.

SIR,—In the report which occurs in THE LANCET of Nov. 26th of the dinner given by the Worshipful Society of Apothecaries to the Lord Mayor and Sheriffs of London on Nov. 22nd your reporter has mistaken the historical allusions of the Lord Mayor when proposing "The Health of the Worshipful Master." You report his lordship as saying "in its early days the society included in its livery grocers, who, however, objected to associating their business with drugs, and so they founded a company of their own." I was present at the dinner. What the Lord Mayor did say was in accordance with the facts, which are just the other way about, the Society of Apothecaries having been formed from the Grocers' Company.

The first corporate body of which we know anything was the Gild of Pepperers which came into existence without a licence, and is mentioned in the Pipe Roll of 1179–80, and which was allied with the Spicers. This Guild ultimately fell into difficulties, and in 1345 some Pepperers founded a new fraternity of Pepperers, which was to include Pepperers of Soper's-lane and Spicers of the ward of Cheap, as well as other members of these two trades or mysteries who dealt in peppers, spices, and drugs. In 1373 the name Grocer was first applied to this Company.

In 1428 the first charter was granted by Henry VI. to the Company of Grocers. In 1562 "the Apothecaries" are spoken of as "Freemen of the Company"—i.e., Grocers. In 1607 the third charter of the Company of Grocers included the Grocers and Apothecaries as one incorporate body. In 1615 the Apothecaries petitioned the King

for a separate incorporation, which was granted in 1617. This was part of a general movement of the time to separate callings which bordered on professions from those which were trades—e.g., the Scriveners and the Musicians; although the Surgeons were not successful in getting separated from the Barbers until much later, in 1745. In 1701 a case was carried on appeal to the House of Lords *re* a Mr. Rose, which settled once and for all that an apothecary was able legally to practise medicine, and that he was entitled to visit and prescribe for a patient as well as prepare medicine for his treatment.

Since that date an apothecary in England has been a qualified medical practitioner, and for nearly two centuries the bulk of the general practice of the country was in his hands.—I am, Sir, yours faithfully,

THOMAS CARR, M.D. Durh.,
A Liveryman of the Worshipful Society of Apothecaries.

Blackpool, Nov. 26th, 1910.

BRITISH MEDICAL BENEVOLENT FUND: SUPPORT URGENTLY NEEDED.

To the Editor of THE LANCET.

SIR,—At the last meeting of the committee I had to report that the grant account on the bank was overdrawn to the extent of £250. In spite of this the committee had to deal with so many and distressing applications that the sum of £300 more was voted, with the result that the deficit now amounts to about £550. Fortunately we have been able so far to meet these demands out of the reserves accumulated at the time of our special appeal two years ago. There is now but little more left, and unless further supplies are quickly forthcoming it will be necessary to refuse help to many deserving cases, and that at the time of year when help is most needed and applications most numerous. We spend all we have, but we cannot spend what we have not got.

I appeal, therefore, to members of the profession to come to the support of the Fund and save it from the pain and reproach of having to refuse relief for want of means. Subscriptions and donations may be sent to me. *Bis dat qui cito dat.*—I am, Sir, yours faithfully,

SAMUEL WEST, M.D. Oxon.,
Honorary Treasurer, British Medical Benevolent Fund.

15, Wimpole-street, London, W.

"606."

To the Editor of THE LANCET.

SIR,—We beg to inform you that we are placing the "Ehrlich-Hata" arsenic compound dioxydiamidoarsenobenzol, generally known as "606," on the market about the middle of December next, under the denomination "Salvarsan."

As it is absolutely impossible for us to answer personally all the inquiries which medical men are sending us daily from all parts of the United Kingdom, we should esteem it a great favour if you would extend the hospitality of your esteemed journal to these lines in order that the above fact may be made known to all your readers. Thanking you in advance,—We remain, Sir, yours truly,

PRO MEISTER, LUCIUS, AND BRÜNING, LTD.,
ERNEST SCHOLL.

London, E.C., Nov. 28th, 1910.

PSORIASIS FROM A BACTERIOLOGICAL POINT OF VIEW.

To the Editor of THE LANCET.

SIR,—I have read with interest Dr. Serrell Cooke's note on this subject, published in last week's number of THE LANCET. On looking through my microscopic sections I find bodies in the so-called epidermal abscesses of psoriasis which I now think are the stumpy bacilli which he has found so constantly in his recent investigations.

I must congratulate both Dr. Cooke and Mr. Garner (the bacteriologist at St. John's Hospital) on their labours, which seem so promising. That I am prepared for the parasitic theory of psoriasis to be proved will be seen from the following abstract of my remarks made in the discussion on psoriasis at the Manchester meeting of the British Medical Association, published in the *British Medical Journal* of Oct. 25th, 1902, p. 1332:—

> Dr. Eddowes thought that they had not got to the end of staining methods, from which they might still expect much without surrendering the position to chemistry. He had found in a case of psoriasis (guttata) a spindle-shaped organism in a sebaceous gland and large micrococci in the mouth of the related hair follicle which formed the centre of the early efflorescence. He taught that *pityriasis rubra* did not become superadded to psoriasis, but that one passed into the other gradually. Psoriasis and pityriasis were closely related. The conditions could change from one to the other.

I am, Sir, yours faithfully,

ALFRED EDDOWES, M.D. Edin.

Wimpole-street, W., Nov. 29th, 1910.

ROYAL SOCIETY OF MEDICINE: ELECTRO-THERAPEUTICAL SECTION.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 29th last, p. 1319, under the heading "Röntgen Society," it is stated that this society is "the parent society of the Electro-Therapeutical Section of the Royal Society of Medicine."

At the request of the council of this section we are writing to ask if you will kindly contradict this statement. The Röntgen Society, consisting largely of lay members, was founded to study the physical side of the Röntgen rays, and is in no way a medical society. The British Electro Therapeutic Society was founded shortly afterwards to study the medical aspects and was a purely medical society. It is this society which was the parent of the Electro-Therapeutical Section of the Royal Society of Medicine.

We are, Sir, yours faithfully,

REGINALD MORTON,
G. HARRISON ORTON, } Honorary Secretaries.

Nov. 22nd, 1910.

SURGICAL INSTRUMENTS AND HOSPITAL PATIENTS.

To the Editor of THE LANCET.

SIR,—The question of the supply of surgical instruments and appliances is one that presses heavily on all societies dealing with the relief of the sick poor, and as a contributor and worker in connexion with one or two of such bodies I should be grateful if you would allow me space in your columns to put some aspects of this matter before the "profession."

The position of any person or society that is asked to contribute funds for the supply of a surgical instrument is one of some difficulty. As "lay persons" we are incompetent to criticise the decisions of the surgeon, and our business as charitable agents is to carry out his instructions and to act on the supposition that all expenditure ordered is essential. It is clear that any other attitude would be quite impossible and inevitably lead to most undesirable friction. But a great responsibility on this very account is thus laid upon the surgeon, for it depends upon him whether the circumstances of the family and the degree of benefit to be derived from the instrument are taken into account or whether it is ordered irrespective of any such considerations.

Do surgeons realise that this responsibility is theirs? Many of them certainly do, and experience has probably shown these that appliances suitable to wealthy patients, where every aid to remedy defect is desirable, are not always justifiable for the poor. Instruments given free are too often carelessly used and quickly destroyed, or even never worn at all; but when patients are too poor to pay even a small proportion of the cost themselves they have to be so provided, and it is the business of charity to find the money somehow. Wherever possible, however, patients should be asked to pay a little in proportion to their means, and I would submit that we are justified in asking those who prescribe to bear in mind that it is not only the wealthy and charitable public who are called upon to put their hands in their pockets, but in almost every case the patients themselves who have to share the cost and incur a debt which, in addition to the many other expenses of illness, they can often ill afford, and which should not be put upon them unless absolutely necessary.

I am, Sir, yours faithfully,

SOCIAL WORKER.

Nov. 22nd, 1910.

THE GERMAN ANTI-QUACKERY BILL.

(FROM A SPECIAL CORRESPONDENT.)

PRACTICALLY coincident with the publication by the British Privy Council of the Blue-book on unqualified medical practice comes the news from Germany that, after years of agitation and many ineffectual attempts to deal with this thorny subject, the field of activity of the quack and the sale of secret remedies is about to be placed on an established legal basis by a uniform law throughout the whole of the German Empire. The Bill of "a law against abuses in the healing *trade*" has received the sanction of the Federal Council, and is now before the Reichstag, after it has been before the health boards of the various States and discussed by the public for no less than two and a half years.

Scope of the Bill.

At present there are no restrictions in the German Empire regarding the practice of medicine; any person may try his prentice hand in curing others, only he may not assume any title or otherwise give rise to the belief that he is the holder of a qualification, and the pharmacists are forbidden to sell a number of drugs except when prescribed by qualified practitioners. Of course, the lay healer has to be particularly careful not to come in conflict with the many laws which deal severely with errors caused by culpable neglect or want of proper knowledge, and the recent proceedings by the State procurators against quacks have been based mostly on the latter, particularly on the law regarding the causation of bodily injury by culpable negligence. In the introduction to the new law, it is distinctly stated that it is not in the Government's intention to return to the former condition of restricted medical practice: "Any law forbidding the practice of medicine by any but qualified persons would only tend to make the quacks work more in secret and therefore less open to control; it is the secrecy in the business of a quack that in the eyes of the public surrounds it with a halo of mystery and promotes the business and prestige of the quack." The present Bill tries to strike the golden medium, and is intended to give the authorities a weapon to take more stringent measures, when necessary, against certain individuals.

The law under discussion will regulate the quack's business to a certain extent. Every person desirous of treating ailments or bodily defects in man or beast as a *trade* (it is interesting to note that they are distinctly designated as "traders") must, before opening his business, in writing inform the local authorities of his intention and give full particulars concerning his education, former occupation, and life. He will be required to keep books as other traders, which will be open to inspection, and he will be obliged to give full information, when required, regarding his methods of treatment. The licensed quack is forbidden to treat by letter, to adopt mystic practices, hypnotism, or use other than purely local anæsthetics. He is forbidden to treat infectious diseases which are dangerous to the whole community, *including cancer* (this is new). The Federal Council will be empowered to forbid the treatment at its discretion of certain ailments in man or beast, as well as the use of any particular mode of treatment. Permission to continue the exercise of a quack's trade may be withdrawn by the authorities whenever they have grounds to believe that the public health is being endangered or the life of animals jeopardised by his methods or when his clients are being exploited by swindling practices.

In view of the practically universal complaints about a falling birth-rate, it is of interest to note that by this law the Federal Council will be empowered to forbid entirely or to restrict the sale of appliances to prevent conception or induce abortion. The quack will be forbidden to supply medicine or appliances, or to instruct his clients to obtain the same from certain persons. An extremely wise provision has been included which makes it possible to forbid the sale of any infants' food or other "foods" if their use is likely to prove injurious to health, or if they are marketed in such a way as to deceive and exploit the public. The quack who makes publicly false statements regarding cures, or who attempts to deceive his clients by false statements as to the value or effects of the procedures he recommends will be liable to one year's imprisonment and a fine of £250, or either of these penalties alone.

To assist the Federal Council in the execution of this law the Chancellor will appoint a commission consisting of members of the Imperial Board of Health, appointed for a period of five years. Persons who wish to appeal against a decision of the Federal Council will be given an occasion of defending their aspect of the case before this commission of experts on the whole subject.

Measures as to Advertisements of Secret Remedies.

In dealing with the traffic in secret remedies the new law lays the axe at its principal support—advertisement. The proposal, often advanced, that the Government should examine every secret preparation before it is allowed to be placed on the market has been dropped; it would, it is stated, imply a certain guarantee of its virtue and value and thereby throw too great a responsibility on the authorities. On the other hand, the Federal Council will have the power to forbid the sale and importation of any preparations, the unrestricted sale of which is likely to prove detrimental to the public health or pocket. However, the principal attack is to be delivered against the advertisements of manufacturers of secret remedies. The measures to be adopted are, from a British point of view so accustomed to the prominent display in the daily press of the supernatural virtues of Somebody's Pills, very drastic; it will be a punishable offence to make any untruthful statements regarding the value, effects, origin, or composition of any remedies or appliances advertised to the public; and, this is the main point in the whole measure, it will be forbidden to distribute or bring to the public notice any testimonials, recommendations, expressions of thanks from clients, opinions of experts, and similar statements regarding any secret remedy. It will also be forbidden to circumvent the above provision by drawing attention to articles contained in books or pamphlets bearing in any way on the preparation. If this were applied in Great Britain, what a different aspect would the morning paper not assume. No more grateful patients "given up by the doctors," no more pictures to form a gallery of the "saved from death's door," who have incidentally contributed to the country's finances.

Present Position of Quackery in Germany.

In conjunction with the above Bill some remarks on the present position of quackery in Germany may prove interesting. The number of quacks in "practice" in Germany can only be estimated, as there is at present no special legislation requiring them to report their trade to the authorities. It is, however, assumed that the total is not wide of 15,000 persons engaged in this lucrative undertaking. That it is a very good paying business has come out in the course of several trials during the past years in which a quack has played the rôle of protagonist. The renowned shepherd, Ast, received about 500 patients daily—in fact, at certain hours of the day the trains were crowded with his "patients." Not to be forgotten is the extensive treatment by correspondence also indulged in. One quack was so overrun with patients that he found it necessary to introduce an automatic machine; the client placed in the machine a 10 pfennig piece (1½*d.*) and received a ticket with a number on it denoting his turn to appear before the gifted healer.

As regards the income derived by these quacks, the trials in which they have figured, and also some collisions with the income-tax authorities, yield a picture of the value of an "unqualified practice." We find mention made of annual incomes of £12,000, £6000, £5000 "at least," £3000 annually during 15 years, down to a mere £40 a month. What is the most surprising aspect of the whole question, and which is especially brought into prominence by the authorities, is the fact that even the poorest will find means to pay for the services of a quack, and in all cases that have come to light the fee of the quack is considerably above that of the qualified practitioner. The average fee was found to range between 3*s.* to 5*s.*, for a consultation by letter 5*s.*, while others are made to pay a deposit of several pounds, for which they will be treated for a certain time. Some extraordinarily high sums have been paid to quacks for a single course of treatment, usually ending disastrously for the patient.

THE SOUTH AFRICAN MEDICAL CONGRESS.

(FROM A SPECIAL CORRESPONDENT.)

THE Twelfth South African Medical Congress assembled in Cape Town on Oct. 31st and remained in session until Nov. 5th. There had been considerable doubt as to the wisdom of the local organising committee in arranging for Congress to meet at a time when all sections of the South African public were enjoying the festivities arranged in connexion with the opening of the new Union Parliament. Events proved, however, that these doubts were not justified, for not only was there a record attendance at Congress, but much really good work was got through in spite of many social functions to which members were invited.

As readers of THE LANCET may remember, attention in a recent number[1] was directed to the fact that public health matters in South Africa were not receiving due recognition from those in authority, and that the only strong health department in the Union—namely, that of Cape Colony—had been abolished instead of being taken as the model from which a proper health department for the Union could be evolved.

Sir Kendal Franks of Johannesburg has earned the gratitude of the profession in South Africa by visiting the larger centres and endeavouring to bring the different medical societies into line so that the Union Government could be approached; and so that the views of the profession in regard to the administration of public health and other matters of general interest could be urged upon its attention. During Congress Sir Kendal Franks's labours were crowned with success, for delegates from each medical association met and agreed to the following resolutions, which were carried unanimously through Congress with instructions to the Standing Committee to see that they were brought prominently before the Government:—

1. That a portfolio of Public Health be created, to be held, if need be, in combination with some other portfolio.
2. That a medical officer of health for South Africa be appointed, who shall be directly responsible to the Minister, and be the sole administrative head of his department. That he be a qualified expert in his department, and that his actions shall be confined to public health matters.
3. That a Medical Council for the union shall be created which shall be chiefly elective, and shall have control over the admission to the practice of medicine, of dentistry, of midwifery, and of nursing, and shall have control of the discipline of these professions.
4. That upon any change of policy on medical questions other than those of public health, or upon any question affecting the status of the profession, the Medical Council shall be consulted.
5. That there shall be an adequate representation of medical men on all boards and committees which have to do with the establishment, maintenance, and management of hospitals under the Provincial Councils.

The importance of these resolutions needs no emphasising, Stating as they do the unanimous desires of medical men in South Africa, and can the Government be induced to act upon them they will stand as *the* most important feature of this Congress. The need for a Minister of Public Health and a properly organised department was referred to repeatedly throughout the Congress—at the official opening ceremony by H.R.H. the Duke of Connaught, in the able presidential address by Dr. C. F. K. Murray, at the banquet by Sir Kendal Franks, and in several papers and discussions arising therefrom, particularly in the Public Health Section. It is to be hoped that with the profession united, as it is for the first time on these matters, the Government will see fit to accede to its wishes, and if not steps are likely to be taken to have the resolutions brought to the notice of Parliament.

Resolutions Nos. 3 and 4 are also of great importance to the profession, for hitherto the elective element in the four Medical Councils of the different provinces has not been sufficiently strong, and it is hoped that the unified Medical Council may consist principally of elected members. Moreover, in practice, it has never hitherto been the custom of the different Governments to seek the advice of the Medical Councils on matters of vital interest to the profession as a whole, but they have usually sought advice from medical men in Parliament or outside who in no sense could be said to represent the profession. The fifth resolution is of importance in the Transvaal alone, for in the other provinces the medical staffs of hospitals have as a rule been adequately represented on hospital boards.

A number of other resolutions were passed by Congress, but those I have mentioned are considered to be of vital interest in South Africa, and will be pressed on the Government by every legitimate means available. It is understood that they will be accorded the support of the Opposition and a small section of the Government party, should it be necessary to bring the matter actually into the political arena.

The papers read at the Congress were generally of a higher scientific value than at former South African Congresses, and though it is invidious to mention any paper where so many are of special merit, the paper on Paratyphoid Fevers in South Africa, by Major J. G. McNaught, R.A.M.C., is worthy of particular attention. A *résumé* of the papers will be published in book form shortly as "Transactions of Congress." The attendance at Congress numbered 129.

[1] THE LANCET, Sept. 17th, 1910, p. 897.

THE ROYAL SOCIETY OF MEDICINE

THE annual dinner of the Royal Society of Medicine was held at the Connaught Rooms of the Freemasons' Hall, London, on Nov. 29th, the President, Sir Henry Morris, being in the chair. A very large and representative gathering assembled at the dinner, and among the numerous guests were the Lord Mayor of London, Lord Ilkeston, Lord Blyth, Sir Thomas Barlow, Sir W. S. Church, Sir Francis Champneys, Sir James Reid, Sir James Porter, Alderman Sir T. Crosby, Sir A. Pearce Gould, Lord Justice Fletcher Moulton, Mr. Justice Lush, Sir Joseph Dimsdale, Sir Almeric FitzRoy, Sir Richard Douglas Powell, Sir W. Treloar, Dr. C Theodore Williams, Mr. Charters J. Symonds, Mr. Whitaker Thompson (chairman of the London County Council), Professor M. J. M. Hill (the Vice-Chancellor of the University of London), Mr. Cowell the secretary, and Mr. Victor Plarr librarian, of the Royal College of Surgeons of England, and Dr. Squire Sprigge (the Editor of THE LANCET).

Sir JOSEPH DIMSDALE, in proposing the toast of "The Society," said they owed much to science, and still more to medical men who devoted themselves to finding out the mysteries of the human body. He then sketched the history of the Royal Society of Medicine, and showed how world-wide its influence was. Its members, he said, now numbered 3300. Mr. Macalister found 800 members when he joined the society, and had worked it up to its present prosperous condition. Sir Joseph Dimsdale concluded by wishing success to the new building of the society's premises.

Sir HENRY MORRIS, in replying to the toast, described the services rendered by Sir William Church to the amalgamation of the various medical societies into the Royal Society of Medicine, and explained that the council of the society had acquired the new site in Henrietta-street for the purpose of erecting new premises because the society had outgrown the accommodation required. Sir Henry Morris's speech was an eloquent exposition of the good that could be done by a great medical society, and was obviously intended to arouse that feeling in the medical profession.

After a brief interval, which was occupied by an interesting display of blood pathology through the cinematograph, the toast of "The Guests" was happily proposed by Sir R. DOUGLAS POWELL and acknowledged by the LORD MAYOR of LONDON, Lord Justice FLETCHER MOULTON, and Sir THOMAS BARLOW.

DONATIONS AND BEQUESTS.—The late Mr. Henry Andrade Harben of Newland Park, Chalfont St. Giles, chairman of the Prudential Assurance Company, Limited, has bequeathed £1000 for the endowment of a bed in St. Mary's Hospital, Paddington, £1000 for the Medical School of that hospital, and £500 to Queen Charlotte's Lying-in Hospital.—The Glasgow Western Infirmary has received an anonymous gift of £3500 for the purpose of providing an operating theatre in the new wing.—The Royal Dental Hospital, Leicester-square, London, has received £100 from Mr. R. McWhirter, as trustee of the estate of the late Mrs. Adelaide Roberts.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE annual Huxley lecture was delivered on Nov. 23rd by Professor Percy Gardner of Oxford, who took for his subject "Rationalism and Science in Relation to Social Movements."—The returns of the number of new students show that 25 have entered for the full medical course and 10 for the dental course. Last year there were 24 medical students and 10 dental students. A significant fact is that of the 25 new medical students this session 17 are men and 8 women. This is a considerable increase in the number of women students.—The annual medical dinner will take place on Dec. 6th. The chair will be occupied by Dr. T. S. Short, physician to the General Hospital, and the principal guest will be Lord Ilkeston, consulting physician to the General Hospital.

Hospital for Skin and Urinary Diseases.

An electrical plant for the treatment of lupus, cancer, and other skin diseases was first installed in this hospital nine years ago, but owing to the growth in the importance of the department and the increase of patients it has been necessary from time to time to enlarge the accommodation. A new and well-equipped department has now been constructed in the basement of the building at a cost of £2000. The plant installed includes three complete sets of X ray apparatus for purely therapeutic work, these being capable of adjustment to give varying qualities of Crookes tube emanations. A shield consisting of a sheet of lead a quarter of an inch in thickness and perforated in one place is interposed between the patient and the tube. The operators are shielded behind screens lined with sheet lead and furnished with windows of thick lead glass. There are Finsen-Reyn and Lortet-Genoud lamps, and the high-frequency apparatus is by Gaiffe of Paris, and is the most powerful of its kind. For rapid radiographs and diagnostic purposes a coil is provided capable of taking a current of from 60 to 70 ampères at 220 volts. Electrolysis and ionisation are other forms of electrical treatment provided, and there is also a room for complete bacteriological and chemical examinations. The department is under the control of Mr. A. A. Russell Green.

Nov. 29th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Royal Southern Hospital: New Out-patient Department.

AN extensive and important addition to the Royal Southern Hospital was inaugurated on Nov. 21st, when Mrs. Adamson, wife of Mr. William Adamson (the president of the hospital committee) opened the new out-patient department, which at considerable expense, has been erected in Caryl-street, opposite the hospital proper. For many years past the old out-patient department—which dates back to the opening of the restored hospital in 1872—has been altogether inadequate for the requirements of the district in which the Royal Southern Hospital operates. That district has now a population of about 340,000 persons. The fact that the old out-patient department has overgrown its resources, as proved by the attendances having increased from 12,500 in 1873 to 45,000 last year, argues the necessity for further out-patient accommodation. Some 20 years ago the committee took steps to raise funds for the purpose of acquiring the site facing the hospital in Caryl-street. This was successfully accomplished and the property purchased, although further exertions on the part of the committee to provide for a building fund met with little response. In 1907, however, the corporation, in compliance with an application from the honorary treasurer of the hospital, obtained parliamentary powers to make a grant of £4000 towards the cost of the new scheme. The civic gift stimulated the generosity of the citizens, who quickly subscribed a sum of £4500, which represented the additional amount required to cover the cost of the building. The new out-patient department is substantially built and of pleasing appearance. Externally the building is of red Ruabon brick with Portland stone dressings, the two central pieces in the front elevation being surmounted with stone finials. A large, well-lighted and well-ventilated central waiting-room, planned to accommodate 200 persons, is approached by two entrances—one for patients and the other for the staff. A semicircular plastered ceiling, free from projections of any sort, effectually prevents the harbouring of dust. This hygienic principle, in fact, has been closely observed throughout the building. On the south side stands the isolation-room with a separate exit to the street, a surgical dressing-room, three consulting-rooms, and a room containing foot and air baths. Similar accommodation is afforded on the north side, with the substitution of a dental-room for the isolation-room. Retiring-rooms and lavatories for the medical staff and nurses and a dispensary are situated on the east side. On the west side are to be found an operating-theatre with a recovery-room adjoining, in addition to a dark room for eye, throat, and nose examinations, and a consulting-room for those special departments. A well-lighted and airy basement provides another waiting-room, around which are situated an X ray room, a developing-room, and the skin department, with consulting- and bath-rooms, a massage- and exercise-room, and a plaster-bandage room. Here also is placed the inoculation department, with a splint-room and a cryotherapy, or freezing, room. The foot and arm baths represent quite a recent addition to hospital plant, and will be of great utility in facilitating the removal of old dressings. The opening ceremony was attended by the Lord Mayor and Lady Mayoress and a large concourse of citizens.

Diplomas in Tropical Medicine; Support from the University of Liverpool; Continued Prosperity of the University.

The memorial presented at the opening of the session of the General Medical Council advocating the recognition of the Diploma of Tropical Medicine as an additional registrable qualification was signed by Sir Rubert Boyce (the Dean of the Liverpool School of Tropical Medicine), Professor Ronald Ross, Dr. J. W. W. Stephens, Mr. R. Newstead, Dr. W. T. Prout, C.M.G., Dr. J. L. Todd (late director of the Runcorn Research Laboratories of the Liverpool School of Tropical Medicine), Dr. Charles J. Macalister, and Dr. William Carter (emeritus professor of materia medica at the University of Liverpool). The pro-Chancellor of the University, presiding over the annual meeting of the University Court of Governors, held in the Town-hall on Nov. 26th, spoke of the continuance of the University's prosperity alike as to the number of students, the number of new chairs, and the advancing standard of work required. He also laid stress on the broadening of the scope of the work of the University, as evidenced by the Tropical School of Medicine, the Town-planning Department, and the School of Social Service, and appealed for £3000 necessary to modernise the equipment of the Department of Electro-technics. The Lord Mayor, the Lord Bishop, Sir William Forwood, Sir Edward Russell, and others testified to the valued services of the University.

Nov. 29th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Opening of the New Wing.

AT the opening of the new wing of the University by Lord Winterstoke, Pro-Chancellor of the University, the proceedings began in the large hall of the University, where the Bishop of Bristol conducted a short service. Then came two admirable speeches by Lord Winterstoke and Dr. T. Herbert Warren, Master of Magdalen College, Oxford, and till recently Vice-Chancellor of Oxford University. The former gave a most interesting retrospect of the progress of higher education in Bristol as he had known it in his lifetime, and a forecast of the place which the modern universities are destined to fill in our national life. Dr. Warren's eloquent tribute to the virtues of Bristol, his native city, contained among others the penetrating idea that a modern university founded in an ancient and historic city should cultivate in some measure that spirit of tradition which in the older University had proved itself so powerful an educational force, as well as the practical and utilitarian point of view which characterises the modern Universities.

After these addresses most of the company moved in a procession through University-road and Woodland-road to the main entrance of the new wing; the chairman and members of the University council were preceded by the bedells, with their staves of ebony and silver, and followed by the Lord Mayor and corporation of Bristol, the master and wardens of the Society of Merchant Venturers, and the Senate and staff of the University. At the same time Lord Winterstoke, the Bishop of Bristol, the treasurer, and certain of the guests, preceded by the mace, passed through the corridors from the old into the new building. The outside procession having reached the door the Lord Mayor gave a short address, in which he exhorted the undergraduates to be worthy of their University, and then the Right Hon. Lewis Fry knocked three times on the door, which was opened from within by Lord Winterstoke with a silver key suitably inscribed. The procession then entered the building to inspect it.

The University Conversazione.

On the same evening the new buildings which were opened in the afternoon were exhibited to about 1500 guests at a conversazione.[1] Happily the weather was fine, and the guests were able to pass into the reception hall where they were received by the Right Hon. Lewis Fry, Sir Isambard and Lady Owen, and others, without the discomforts of dampness which at one time threatened. So many things were on view that it was impossible for anyone to see everything; but by means of ingeniously planned routes, indicated by arrows of different colours on the walls, everyone was directed to those exhibits in which he was specially interested. Among the most striking of these were the tele-photographic apparatus, the action of which was demonstrated by the inventor, Mr. T. Thorne Baker. A tele-writer apparatus in action was also shown. Captain F. P. Mackie, I.M.S., an old Bristol student and a member of the Sleeping Sickness Commission for Uganda, lectured on his travels, with many lantern illustrations; and Professor A. F. Stanley Kent gave a demonstration of high frequency currents. In another room there was a "Sahara scene" arranged to show various kinds of desert vegetation, while the small hall of the University was filled with Antarctic curios brought back by the Shackleton Expedition. It would be impossible to catalogue all the minor attractions of the conversazione, but two or three were of special interest to medical visitors, among them a most ingenious demonstration of the part played by flies as carriers of disease, and a graphic demonstration of the electrical variations in the active human heart by means of Einthoven's string galvanometer. No efforts had been spared to make the evening successful, and everyone carried away a very pleasant impression of the new wing and its great possibilities.

A Colston Chair for the University of Bristol.

A letter has appeared in the Bristol papers above the signatures of the Vice-Chancellor and those of the president and treasurer of the Bristol University Colston Society. This society has for some years contributed large sums to the funds, first of University College and now of the University. The letter was published on the Colston anniversary, on which certain charitable societies founded in memory of the great Bristol philanthropist, Edward Colston, commemorate his birthday by banquets (two of which, the Anchor and the Dolphin banquets, have a political importance). As the writers point out, it is not just to the memory of Colston to honour his name by means of charities only, for of his own very large donations to various public projects more than half was devoted to the furtherance of education. They ask that the present annual contribution of about £450 which their society makes to the University funds shall be raised by addition of new subscriptions to £1000, that a sum adequate for the maintenance of a "Colston chair" may be provided.

Bequests to Charities.

The Bristol papers announce that the late Dr. C. W. Belfield, formerly of Old Market-street, Bristol, has left the following legacies among others: to the Bristol General Hospital, £5000; to the Bristol Royal Infirmary, £100; and to the Bristol Eye Hospital, £100.

Nov. 29th.

[1] We are publishing a description of these buildings in a later issue.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Representation of Aberdeen and Glasgow Universities.

A MEETING of the Executive Committee of the Aberdeen University Liberal Association was held on Nov. 25th, when it was unanimously agreed—

That it having been intimated that Professor Ogston is willing to stand as an independent candidate in the interests of science and education, the members of the Executive Committee of the Aberdeen University Liberal Association, recognising his unique qualifications as a University representative, are of opinion that it is not expedient to bring forward a candidate at this election.

Professor Ogston has, however, written stating that he does not intend to offer himself as a candidate for Parliamentary honours. In a letter to Professor J. A. Thomson Professor Ogston sets out the reasons which have weighed most with him in resolving at present to abstain from seeking to represent the joint constituency. He writes: "Throughout the country the present political crisis is arousing an unusual strength of partisanship, which will compel most voters to select that candidate who will most determinedly resist the side which that voter opposes, and candidates like myself, in favour of moderate measures, will have far less prospect of favourable consideration than has been the case in any General Election within my memory. Had time sufficed for representing to the constituencies the advantages moderation offers in solving the crucial problems before the country, and especially of explaining the increasing importance to our Universities of having the interests of science, education, letters, and research regarded as the main object of their chosen Member's activities, there might have been a prospect of success for one holding such views as I. But no energy and work can possibly accomplish this, to even a moderate degree, in the available time, and the defeat of such a candidate as I should have striven to be would be a foregone conclusion. The effort would be wasted, and what is more momentous, the defeat would tell in any future contest on any candidate holding like views. I feel assured that consideration will give to these reasons a cogency they may not, at first sight, seem to possess, and that it is in the real interest of the universities that I should not stand as an independent candidate at present. There are, in addition, domestic reasons that I need not detail which have much weighed with me in forming my resolution. I can only further say that I feel a gratitude beyond my power to put into words that I should have been thought of by you and others who love our universities in connexion with their membership."

Dundee Royal Infirmary Staff and the Time-Gun.

On account of the objections taken by the staff of Dundee Royal Infirmary, the charge in the time-gun has been reduced from 4 pounds to 2½ pounds, but still the infirmary officials are not satisfied. The works committee of the Town Council has decided, however, to continue the smaller charge meantime.

Anatomical Society of Great Britain and Ireland.

At the annual general meeting of the members of the above society, held on Nov. 25th at Guy's Hospital, London, Professor Robert W. Reid, professor of anatomy in the University of Aberdeen, was elected President for the ensuing year, and his senior assistant, Dr. Alexander Low, was elected Scottish secretary of the society.

(FROM OUR OWN CORRESPONDENTS.)

Health and the Primary Schools.

THE insanitary condition of many of the Irish primary schools has often been the subject of criticism, for many of the schools are overcrowded, and heating, ventilation, and water-closet accommodation are insufficient. It is now some years since the Irish Government made a promise to provide funds to aid in remedying this state of affairs, but so far the Treasury has failed to make the promise good. No one can defend the present state of the

school buildings. In an address delivered last week Professor Barnes, professor of agriculture in Trinity College, Dublin, commented on certain other factors of school life which act adversely on the health of the children. The minimum school age in Ireland is three years. It is no uncommon thing for infants of 3 and 4 years in Ireland to be led to school, where they have to sit for long hours, possibly in wet clothes and perhaps hungry. As a rule, no attempt is made to teach them anything but "to sit quiet," which, as Professor Barnes rightly says, is the very thing nature wishes them not to do. He maintains also that the school hours are too long. For five hours or more of the best of the day the children are deprived of fresh air and sunshine—the two great enemies of disease. There can be little doubt, as Professor Barnes says, that these factors, working on the childhood of Ireland, are responsible for that weakening of the stamina which keeps the tuberculosis rate so high in the country.

Recent Government Appointments.

Some criticism has been roused by the appointment of a medical member of the General Prisons Board, Ireland, recorded recently in THE LANCET (Nov. 12th, p. 1451). The criticism is not based on personal grounds, but on the fact that a member of the Prisons Service has not been selected. Since the prisons were taken over by the Government in 1878 all the successive medical members of the Prisons Board, with one exception, have been Local Government Board inspectors, and none of them have had any previous knowledge of prison work or of criminology. There are many medical men of high standing employed as prison surgeons, and it is not clear why promotion to the General Prisons Board has not come their way. In contrast to this is the practice in the Local Government Board, where two recent appointments of medical inspector have been given to gentlemen with experience of the Poor-law service. One of them, Mr. C. J. MacCormack of Athlone, had been for some 30 years a dispensary medical officer, and the other, Dr. Brian O'Brien of Belfast, had formerly been in the dispensary service and latterly a police surgeon.

The Royal Academical Institution, Belfast.

This old school—at which so many North of Ireland men have received their early education—had a series of centenary celebrations last week, one of which was specially enjoyable, the dinner given on Nov. 22nd, in the City Hall, by the Lord Mayor of Belfast (Mr. R. J. McMordie), who is himself an old Academical. Among the speakers were Sir Samuel Dill, Sir Joseph Larmor, Sir Almroth Wright, and Sir John Byers, all old pupils of this famous school. A centenary volume, giving the story of the school, its foundation, and history from 1810 to 1910, is shortly to be published.

Workhouse Dispensary Relief: Abuse of the Grant in Lisburn.

At the weekly meeting of the Lisburn board of guardians held on Nov. 22nd, Dr. D. C. Campbell, medical officer of the Lisburn dispensary district, reported that medical lines were being issued by wardens or guardians to persons who certainly were not entitled to dispensary relief, and who, from their position, were well able to pay for the attendance of a medical practitioner. On looking over his books he found that before his appointment the average annual issue of lines was 1500, whereas now—and the year was not closed—he had received 2100. He also instanced receiving several tickets a short time ago which were issued in the name of a local guardian, and every one of them was illegal, not being signed by the guardian himself. After a discussion the report of a committee was adopted giving the dispensary committee the power of the board of guardians to cancel tickets of the description given, so as to enable the medical officer to recover costs in the petty sessions and expose such persons through the press.

Nov. 29th.

THE National Food Reform Association are asking Parliamentary candidates for support in the effort to combat physical degeneracy by securing the standardisation of bread, the passing of a Pure Milk Bill, and a Bill dealing with patent medicines, the improvement of the teaching of cookery, and so on. Information may be obtained by sending a stamped addressed envelope to the secretary, 178, St. Stephen's House, Westminster, London, S.W.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Malta Fever Contracted in a Laboratory.

AT a meeting of the Academy of Medicine held on Nov. 15th M. F. Widal, M. Cotoni, and M. Kindberg remarked that goat's milk was the chief, but not the only means of propagating Malta fever. The slightest contact with the Micrococcus melitensis was sufficient to communicate the disease. This microbe was one of the most dangerous to those who had occasion to perform manipulations with it, and there have already been many instances of laboratory infection in countries where the disease prevailed. This misfortune had recently happened in Paris to a man who attended to the cultures in the laboratory of the three bacteriologists above mentioned. The disease followed its ordinary course with "undulating" pyrexia, profuse perspiration, and sharp pains of a myalgic character. The diagnosis was confirmed by the recognition of the Micrococcus melitensis in the blood and urine, as well as by the reactions of agglutination and fixation. Such instances of laboratory infection showed how easily Malta fever might be contracted anywhere and made evident the necessity of precautionary measures. As the agglutination reaction was commonly employed in laboratories for the diagnosis of the disease, it would be advisable to have recourse to cultures killed by the vapour of formol. M. Widal said that as Malta fever was increasing of late years in France the prevention of it ought to engage the attention of the sanitary authorities. It was necessary to make the public understand that the milk of goats should be boiled and that regulations should be made with respect to the importation of the animals. He, moreover, recommended that Malta fever should be made notifiable, as the bacteriological diagnosis of it and the method of transmission were fully known.

Cancer of the Lower Lip treated by Electro-coagulation.

Speaking at the Society of Medical Radiology and Electrotherapeutics recently, M. Fauchie-Villeplée described three cases of cancer of the lower lip which were successfully treated each at a single sitting in the practitioner's consulting-room, and without any subsequent interruption of the patients' ordinary occupations. The operations were performed under local anæsthesia by means of cocaine; deep cicatrisation took place rapidly, and only a very small scar was left. The observations were still too recent for the formation of an opinion as to the ultimate results, but from the point of view of the immediate results, electro-coagulation seemed to present several advantages. For the surgeon the operation was an easy one and did not require much apparatus, while for the patient it was a boon that only a single application was necessary and that little, if anything, had to be done in the way of previous preparation or subsequent attention. Radiotherapy, on the other hand, required several sittings. Surgical excision was not only more complicated than electro-coagulation but required the application of dressings and caused much greater loss of substance.

Ambulatory Treatment of Fracture of the Leg.

At a meeting of the Surgical Society held on Nov. 16th M. Routier presented a report on 15 cases of fracture of the leg treated on the ambulatory system by means of Delbet's apparatus. The cases were communicated to M. Routier by M. Schmid, who said that the results were excellent, both the reduction of the fractures and the retention of the bones in position being quite satisfactory. In some instances there was swelling which necessitated a modification of the apparatus. The duration of the treatment seemed to be shorter than usual, and on the removal of the apparatus the muscles showed no atrophy, neither had the integuments suffered in any way.

Appointment at the Faculty of Medicine.

At the general meeting of the Faculty of Medicine which was held on Nov. 24th Professor Landouzy was recommended for re-election as dean; out of a total of 59 votes 57 were given in his favour.

Treatment of Talipes Equino-varus.

At a meeting of the Pediatric Society held on Nov. 15th M. Jalaguier and M. Lamy showed a child who had suffered

from talipes equino-varus and had been operated on, by *évidement* of the astragalus, an operation which, of course, did not dispense with the necessity for the post-operative measures which were employed in orthopædic surgery. The operation was an easy one, and by far the least serious of those which were applicable to the bones of the foot; it might even be performed on a suckling infant. The loss of blood was insignificant, and risk of infection was avoided by the smallness of the incision in the skin and the absence of any thread or catgut. The correction of the malformation was perfect no subsequent shortening of the foot occurred, and the tibio-tarsal movements were preserved.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Avoidance of Pluralism in Hospital Appointments.

BY a recent change of policy in the making of appointments to private hospitals, a very welcome opportunity of using their knowledge for the public benefit is being given to the large number of *privat-docenten* living in this city. This new departure has for its aim the prevention of multiple holding of offices in hospitals. Hitherto in private charitable institutions the same man has very often filled two similar or even dissimilar appointments, and it has not been uncommon for a professor to occupy the position of consultant for some specialty or other in four or five different institutions, whilst hundreds of *privat-docenten* were condemned to comparative idleness. Now these hospitals have made it a rule to apportion such appointments—they are all honorary only—between two or more of the younger men; this will also hold good in the hospitals conducted by religious corporations, so that in a few years a number of the younger and more active scientific workers will have their appointments. Hitherto, even the posts of specialists for the working men's sick clubs and similar friendly societies have often been the object of cumulation. These appointments, too (they are, of course, not purely honorary, but carry some remuneration with them), will in future be given preferably to comparatively young men not yet holding any other similar post. In that respect the outlook for the better qualified men in Vienna is improving.

Proposed New Regulations for the Management of Hospitals and Public Charities.

The independence of the hospital staff will be seriously interfered with if some new legislative proposals should become law. The circumstances are that the political party now in power in Lower Austria is endeavouring to get into its hands the entire control of the public charitable institutions, including the hospitals and university clinics, under the pretext of financial consolidation of the bankrupt Hospital Fund. The latter fund is utterly inadequate and suffers from a chronic deficit, for which hitherto no remedy has been found, because neither the financial department of the State, nor that of the Empire, nor the municipalities, are willing to take over the indebtedness of the fund amounting to some 16 million kronen (£700,000). A scheme has now been worked out by the financial experts of the ruling party, which would not only provide the money necessary to pay off the debts, but would also ensure working capital for all the hospitals in Vienna and Lower Austria. The scheme necessitates a new tax of 5 per cent. upon all the rates and taxes levied hitherto throughout the area in question—no pleasant news for the public. It would also provide for all these institutions a governing body, which would contain, amongst 32 members, two medical men as representatives of the medical profession. The past history of this political party does not warrant the expectation that it will give considerate treatment to scientific and other medical requirements, and the hospital staff would be at the mercy of an official appointed by the governing body, whereas at present medical influence is nearly paramount in the great majority of hospitals here. It is also intended to introduce the system of whole-time hospital appointments whereby the holders of these positions would be bound never to take up private practice. In this way young medical men would be practically debarred from acquiring hospital experience before settling down in private practice, which would be a very undesirable prospect. Nevertheless, there is great danger that the Bill to this effect will be passed even if without those clauses which are simply impossible; in any case the effect which it would produce upon the medical profession would be so deleterious that a strenuous opposition is being already organised.

"606."

The great interest excited by Professor Ehrlich's discovery of the powerful microbicide termed "606" has been well illustrated in a discussion on its use, which took place quite recently in the Vienna Gesellschaft der Aerzte. The balance of opinion was evidently favourable to the new remedy, although several unpleasant temporary symptoms have been caused by it. For instance, acute neuritis of the vestibular nerve has been observed by Beck and slight pyrexia and malaise by other medical men. Ullmann has found by radiographic investigations that the deposit produced in the tissues by the injection was still present in the third week, the inference being that an injection must not be repeated earlier. In the clinic of von Neusser the action of "606" upon spirilla and spirochætæ has been carefully studied, and it was found that for them the substance was a powerful germicide. The usual dose administered here is from 0·4 to 0·5 gramme (from 6 to 7½ grains), preferably in a neutral solution. It has been tried with good effect in initial stages of progressive paralysis and was very useful in the painful stage of incipient tabes dorsalis. A very interesting communication on this subject was made by Dr. Kobler of Bosnia. In that part of Austria syphilis is very common, but it is easily influenced by mercury and iodides. A systematic investigation has been instituted by the Austrian Government in this new province, and the entire population would in course of time be examined for syphilis. Up to the present date 650 syphilitic patients who had had no treatment have received injections of "606," and were being kept under observation. The experience of several eminent clinicians showed that this substance was, as a rule, more efficacious in the early stages of the disease than the old remedies, and that in inveterate refractory cases it sometimes acted wonderfully well, but that there were a good many cases in which mercury and iodide of potassium could not be dispensed with. Wassermann's reaction was often positive for three or four weeks after the injection of "606," and relapses have been observed in Vienna as early as two weeks after the injection. It was therefore more than probable that the present mode of administration was not yet the ideal one. All the speakers agreed that it was inadvisable to use this substance in advanced cases of meta-syphilitic (systemic) affections of the nerves, and that its exact position in the materia medica has not yet been ascertained.

Nov. 28th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Convalescent Soldiers.

THE following notification has been issued by the Army Department, Principal Medical Officer's Branch, Simla:—

The station selected for the transfer of weakly soldiers to India during the winter instead of sending them as invalids to England are: *Kasauli* and *Subathu* for the reception of cases from the 1st, 2nd, 3rd, 4th, 5th, 7th, and 8th Divisions (except the Presidency Brigade); *Lebong* for the reception of all cases in the Presidency Brigade and Burma; *Mount Abu* for the reception of all cases in the 5th Division, for which Kasauli is not considered suitable. *Ourandhar* and *Khandhalla* for the reception of cases from the 6th Division; *Wellington* for the reception of cases in the 9th Division; *Karachi* for the reception of special cases from the 1st, 2nd, 3rd, 4th, and 7th Divisions. *Colaba* for the reception of special cases from the 9th Division. As regards the 4th Division, the men might in the first instance be interchanged between *Quetta* and *Karachi*, otherwise they should be sent to Kasauli.

The following stations have been reserved for enteric convalescents: Naini Tal for the reception of cases from the 1st, 2nd, 3rd, 4th, 7th, and 8th Divisions, and Jubbulpore, Jhansi, and Mhow. Wellington: An enteric convalescent depôt has been established for the 6th, 9th, and Burma Divisions and for Kamptee and Sitabuldi, also for Mhow and Jubbulpore when accommodation cannot be made available for convalescents at Naini Tal.

Report of the Chemical Examiner and Bacteriologist to the Government of Burma for 1909.

Major F. N. Windsor, chemical examiner and bacteriologist to the Government of Burma, in a report on the work carried out in his laboratories during 1909, shows that the number of articles examined by him has increased from 7274 in 1908 to 17,696 in the year under report. A great deal of the extra work thrown on the chemical examiner was caused by the large consignments of cocaine seized by the Excise Department, as the importation of this drug into British India and Burma has been forbidden except for medicinal purposes. The number of analyses made in the case of suspected human poisoning increased by 25 over the previous year, showing that crime of a nature requiring aid from the expert chemist for investigation is by no means decreasing in Burma. The number of cases connected with bloodshed increased by 57, and the articles by 103, while the percentage of detection was 51·4 as compared with 47·5 in 1908. The number of rape cases was 175, with a percentage of detection of 49·7. In the rainy season it is noted that any method of examining seminal stains frequently failed owing to bacteria invading and obliterating the spermatozoa. Major Windsor directs attention to the unfit condition of his laboratory for both chemical and bacteriological investigations, and Colonel W. G. King, C.I.E., I.M.S., late Inspector-General of Civil Hospitals in Burma, in his covering letter forwarding the report to the Secretary of the Government of Burma, expresses an opinion that the small sum of Rs. 25,000 which it is proposed to allot will be insufficient for the requirements of a laboratory worthy of the province.

Nov. 5th.

Obituary.

ANGELO MOSSO.

THE Senator Angelo Mosso died on Nov. 24th in Turin, at the age of 64. Comparatively short as was his life, he played many parts in the domain of biology, and in all of them acquitted himself with a skill and an address that explain the sense of loss which scientific Italy is feeling to-day. One of a gifted family, he enrolled as a student of medicine in the university of his native Turin, and, after a brilliant graduation, he entered the medico-military service. In this capacity he attended post-graduate courses at sister seats of learning, first in Italy, where for two years he worked with Moriz Schiff, then holding the chair of physiology in Florence, and afterwards in Germany, where he was a diligent student under Ludwig of Leipsic. Thence he proceeded to Paris, and returned in 1876 to Turin, an accomplished physiologist, with special knowledge of the virtues and action of drugs. His Alma Mater, on the strength of this, installed him in the chair of Materia Medica. With the aid of the government and the "Consorzio Universitario" he established in connexion with this professorship the first laboratory of pharmacology in Italy—an initiative since followed up in the sister schools. When Jakob Moleschott, the illustrious biologist and physiological chemist who, under the auspices of Cavour, rehabilitated the scientific bases of medical study in Italy, was transferred from Turin to Rome, Angelo Mosso was chosen to replace him in the Turinese chair—a choice more than justified by the ability with which he maintained the traditions of his Dutch predecessor. His prelections came to be the most frequented of the Subalpine School, and relays of students passed through his hands to fill posts of trust in the biological sciences throughout academic Italy. Honours of many kinds now came to him. He was elected Rector Magnificus of his Alma Mater and communal councillor for the city, in which capacity he did invaluable work in public hygiene and education. A favourite at Court, he was made in rapid succession Commendatore of SS. Maurice and Lazarus, Commendatore of the Crown of Italy, and decorated with the Cross of the Legion of Honour; while as Senator of the kingdom he showed himself an enlightened legislator, particularly in those questions, hygienic and educational, in which he had given such evidence of proficiency in his native city. Scientific distinction also fell to his lot in ample measure. He was a Member of the Academia dei Lincei of Rome (which corresponds to the British Royal Society), and also of a long list of learned bodies, Italian and foreign—the Imperial Society of Berlin having, indeed, elected him Corresponding Fellow only a few days before his death.

Master of a ready pen, he contributed largely and effectively to the literature of his favourite subjects, first on the action of tartar emetic, then on that of chloral, followed by monographs, "Sulle Irritazioni del Cervello," and, not less original and illuminating, "Sul Modo di Scrivere i Movimenti dei Vasi Sanguigni" ("On the Mode of Recording the Movements of the Blood-vessels"), "Sulla Attività Diastolica del Cuore" ("On the Diastolic Activity of the Heart"), and "Sul Modo di Scrivere i Movimenti del Cervello nell' Uomo" ("On the Mode of Recording the Movements of the Brain in Man"). This last work, coupled with his invention of the "strumento misuratore" (measuring instrument) enables us to compute the time, the duration, the degree of a sensation from without transmitted to the brain in the most diverse ways. On the strength of this he rose to the front rank of Italian physiologists and obtained the prize of 10,000 francs awarded for original research by the Accademia dei Lincei. On the lines of this work he published most interesting and suggestive monographs on Sleep, in its physiological and hygienic aspects, to say nothing of treatises on Respiration, on the Movements of the Intestine, on the Systemic Circulation, on the Temperature of the Brain, on the Apparent Death of the Heart, on Respiration in Tunnels, on the Ptomaines, as well as the widely diffused *opuscules* addressed *ad populum* on "Fear" and on "Fatigue."

One great achievement of his busy life was the foundation of the Institute for Nature Study on the Monte Olen, some 9000 feet above sea-level, in which he was loyally aided by brother scientists, Italian and foreign, and also by the subsidies of the home and continental governments. It was in 1905 that, together with a few of his class assistants, he worked at the "Capanna Margherita" (the hut called after the Queen Dowager of Italy, an enthusiastic mountaineer) and carried out his researches on the phenomena of respiration at altitudes above the snow-line. From this took origin the institute, now open for some ten weeks of the last summer and early autumn to nature-students of such nationalities as have subsidised it, and described in THE LANCET of Sept. 4th, 1909, p. 730. Already it has amply rewarded its originator and his coadjutors by the observations taken, classified, and put on record by its *personnel* on zoology, mineralogy, botany, meteorology, and, indeed, on every subject of scientific interest in the Alpine world. It will indeed be the true monument and, in a sense, the mausoleum of Angelo Mosso—a "point of pilgrimage" to succeeding generations of students, compatriot and continental, colonial and trans-Atlantic, intent on doing homage to the mentally gifted and philanthropically inspired investigator, teacher, and counsellor, whose death all Italy and, with her, the brotherhood of science are now mourning.

Professor Mosso's health had been showing signs of deterioration for some years back. A spinal affection had been partially overcome by relaxation of indoor work, only to be succeeded by symptoms of diabetes which still further curtailed the hours spent in the laboratory and indicated the open-air life to which he accordingly devoted himself. Even in these conditions his scientific and eudcational interests found congenial scope. He became, as his colleagues dubbed him, the "Apostle of Physical Exercise," inuring the academic youth to athletic games mainly on English lines and founding football clubs which have already given a good account of themselves "at the goals." The distraction of foreign travel, also prescribed, opened up to him a new field for investigation, and visits to Crete and Sicily fructified in admirable monographs on the treasure-trove of the pre-historic ages. But by this time the intense activity of mind and body was beginning to tell—"the sword was visibly wearing out the scabbard"—and the last few weeks saw him a prostrate invalid, loyally and lovingly attended by all that was most skilful and experienced of the Subalpine School. Gradually the faculties became blunted and the brain ceased to respond, till, on the morning of the 24th, his bed surrounded by his family and his more intimate colleagues,

he succumbed to what the medical bulletin affixed to the University gates calls "œdema cerebrale, originato da intossicazione diabetica." No more imposing funeral than that which closed "the last scene of all" has for many a year been witnessed in Turin, and the *oraisons funèbres*, eloquent and impressive as they were, conveyed but inadequately the sense of bereavement with which all Italians, from the King to the humblest of his subjects, are now mourning Angelo Mosso, "gone over to the majority."

THOMAS FRANCIS SPITTAL CAVERHILL, M.B., C.M. EDIN., F.R.C.P. EDIN.

THE death of Dr. T. F. S. Caverhill of Edinburgh took place at his brother's house at Jedburgh on Nov. 4th. For nearly a year he had been in failing health and unable to undertake active work, but it was not thought that his death would take place so soon. Born at Crichness, in the heart of the Lammermoors, he was the bearer of an ancient Scottish border name. He received his medical education at Edinburgh, where he graduated M.B., C.M. in 1878. In 1882 he was admitted a Member of the Royal College of Physicians of Edinburgh, becoming a Fellow in the following year. He was a resident physician and a resident surgeon of the Royal Infirmary and of the Royal Maternity Hospital, Edinburgh. Later he was physician of the New Town Dispensary and surgeon of the Eye Dispensary, Edinburgh.

For many years Dr. Caverhill was medical officer of health of the county of Haddington. He was greatly interested in army medical matters and held the rank of Surgeon-Colonel in the Lothian and Berwick Imperial Yeomanry. His sympathies for wounded cavalry soldiers were aroused by some public remarks of General Drury-Lowe on the cruel and apparently unavoidable hardships endured in long and rapid cavalry marches through a hostile country during the Egyptian campaign. After many experiments he evolved the mounted ambulance scheme for cavalry wounded, which was favourably commented on by H.R.H. the late Duke of Cambridge. Some of our readers may have witnessed the interesting display of Dr. Caverhill's Mounted Ambulance Company at the Military Tournament in the "eighties."

He was a vigorous advocate of the open-air treatment of pulmonary tuberculosis, and did much to further the "crusade against consumption" in Scotland. He established at his own expense the Manor Valley Sanatorium at Caverhill near Peebles, so that those who could not afford the usual rates of a private expensive sanatorium could, for a moderate fee, secure proper treatment there. With characteristic generosity he often went a step further and dispensed with fees altogether in necessitous cases. He held the traditional high ideals of the profession and constantly went out of his way to relieve other than physical miseries which so often are brought under the eye of a medical practitioner who enjoys the confidence of his patients, and was accordingly beloved to no ordinary degree.

Dr. Caverhill was a lover of all that related to Scottish lore and character, and gathered together a rare collection of prints of Mary Queen of Scots, of her contemporaries, and of her times. The prints being carefully chosen and arranged, form in themselves an interesting history of that remarkable queen. In Dr. Caverhill the medical profession has lost not only an able exponent of our science, but an exceptionally cultivated man, generous, public-spirited, and well-informed.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. N. Manolesco, formerly clinical professor of ophthalmology in Bucharest.—Dr. Gagnière, *professeur agrégé* in the Medical Faculty of the University of Montpellier.—Dr. Hugo Behrens, a German medical officer who wrote a number of novels under the *nom de plume* B. Renz. He was 90 years of age.—Dr. Baynes Walker, formerly professor of medicine at the Woman's Medical College of Pennsylvania in Philadelphia.

PROPOSED COTTAGE HOSPITAL FOR ST. AUSTELL.—About £1500 have now been raised towards the erection of the proposed cottage hospital for St. Austell. The institution is much needed for the district, and it is hoped that the work will shortly be commenced.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. E. Battle (Sections I. and II.), Leeds and University College Hospital; C. B. Davies (Sections I. and II.), Manchester; E. B. Keen (Section II.), Charing Cross Hospital; J. M. Moll (Sections I. and II.), Utrecht and St. Bartholomew's Hospital; W. H. Parkinson (Sections I. and II.), Manchester; and C. J. Thompson (Sections I. and II.), Birmingham.

Medicine.—E. G. Brisco-Owen (Section I.), Cardiff and Royal Free Hospital; A. Cordon (Section II.), Birmingham; and C. B. Davies (Sections I. and II.), Manchester.

Forensic Medicine.—C. B. Davies, Manchester; C. W. Jenner, London Hospital; J. M. Moll, Utrecht and St. Bartholomew's Hospital; and A. J. V. Mathews, St. Mary's Hospital.

Midwifery.—C. B. Davies and W. H. Parkinson, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—H. E. Battle, A. Cordon, C. B. Davies, J. M. Moll, and C. J. Thompson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Genoa:* Dr. Vittorio De Cigna has been recognised as *privat-docent* of Laryngology and Otology.—*Heidelberg:* Dr. Erwin Rohde has been recognised as *privat-docent* of Pharmacology.—*Kiel:* Dr. Arthur Wilke has been recognised as *privat-docent* of General Pathology and Pathological Anatomy.—*Lyons:* Dr. Guillemard has been appointed (after public competition) Professeur *agrégé* of Biological and Medical Chemistry.—*Padua:* Dr. Luigi Maccagi has been recognised as *privat-docent* of Operative Medicine.—*Palermo:* Dr. Vincenzo Greco has been recognised as *privat-docent* of Medical Pathology.—*Pavia:* Dr. Domenico Cesa Bianchi has been recognised as *privat-docent* of Pathological Histology.—*Parma:* Dr. Mario Pelagatti, Professor in Sassari, has been appointed Professor of Dermatology in succession to the late Dr. Mibelli.—*Prague (German University):* Dr. Robert Salus has been recognised as *privat-docent* of Ophthalmology.—*Rome:* Dr. Stefano Mircoli of Genoa has been recognised as *privat-docent* of Medicine.—*Saratoff:* Dr. Pavloff of Kharkoff has been appointed to the Chair of Histology.—*Sienna:* Dr. Luigi Baldassari has been recognised as *privat-docent* of Hygiene.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students of the Royal Dental Hospital of London was held in the Whitehall Rooms of the Hotel Metropole on Nov. 26th. Mr. H. Lloyd Williams presided, and amongst those present were Dr. H. Campbell Thomson, dean of the Middlesex Hospital; Mr. Sidney Spokes, dean of the National Dental Hospital; Mr. L. A. Bidwell, dean of the Post-Graduate College of the West London Hospital; and Mr. H. S. Clogg, vice-dean of the Charing Cross Hospital. The announcement that their Majesties King George and Queen Mary had consented to act as patrons of the hospital was received with hearty applause. In proposing the toast of the past and present students of the hospital and school, Mr. Lloyd Williams having congratulated the prize-winners of the year, went on to say how glad he was to see his old friend, Mr. J. F. Pink, once more amongst them after his severe illness. Having referred to the many difficulties experienced by the staff and students in the early days of the hospital, the chairman said he considered that the new building in Leicester-square was one of the best that had ever been erected for a special purpose. The influence of the hospital was felt by the students in their after work, and all carried with them happy memories of the atmosphere of the old school. Mr. W. A. Maggs, responding for the past students, said that the authorities of the different dental schools worked together without jealousy, both staff and students feeling the greatest pleasure in helping those in need of dental work. The various deans frequently met together and consulted on the best means of assisting dental science as a whole. He hoped in the near future to see a research fund instituted to enable men to devote themselves to this special branch. Mr. F. Quayle, chief prize winner, mentioned that at the present time the students numbered amongst themselves men from South Africa, United States, and Australasia, and the effect of this was to widen the minds of Celts, Saxons, and Colonials alike. In his speech the dean, Mr. W. H. Dolamore, endorsed what the chairman had said in reference to the return of their secretary, Mr. Pink. He felt he could not let the

occasion pass without saying how much they were indebted to Mrs. Pink, who had so ably carried out her husband's work during his enforced absence. Mr. Dolamore alluded to the warm affection felt for the Royal Dental Hospital by its old students. Mr. Bidwell, responding for the visitors, said that no one recognised more than he did the importance of dentistry. Many patients would never have passed through his hands if they had applied in their early days to a dental surgeon. He felt it was more important to teach children the use of the toothbrush than to play the piano. Mr. J. F. Colyer chairman of the Medical Committee, in proposing the health of the chairman, stated that the hospital never had a more faithful servant or the students a more patient teacher. He was in all things a man of good judgment and active sympathy, whose sound rules laid down when he was the first curator of the mechanical department contributed so much to its success. In his reply, Mr. Lloyd Williams referred to the pleasure that the visitors experienced at the "At Home" that afternoon at the hospital. They all appreciated the excellence and great variety of the work done there, and he wished to express on behalf of the old students their indebtedness to the demonstrators for the trouble they had taken.

THE BRITISH MEDICAL BENEVOLENT FUND GUILD.—There was a large attendance at the New Hospital for Women on Nov. 29th, when Lady Frederick Brudenell Bruce presided over the annual meeting of the British Medical Benevolent Fund Guild. The various reports, which were read by Lady Tweedy, Mrs. H. D. Rolleston, Mrs. Hutchison, and Mrs Liveing, showed that much useful work in relieving distress among members of the medical profession and in helping the widows and orphans of medical men had been accomplished during the year. The treasurer's statement showed a balance on the year's working of £163. The reports were unanimously adopted. Lady Frederick Bruce congratulated the Fund on the excellent result of their work and made a special appeal on behalf of the "Father Xmas" branch. Sir William Church, in seconding the adoption of the reports, said that it was impossible for the parent society, the British Medical Benevolent Fund, to adequately deal with many of the distressing cases which came before its notice, and this proved the extreme necessity for the guild through which the personal services of ladies could be given. Various votes of thanks concluded the meeting.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 24th, with Sir Francis Champneys in the chair. A letter from the clerk of the Privy Council requesting the Board to furnish the Lord President with statistics as to the number and distribution of certified midwives in the country for the use of the Austro-Hungarian Ministry of the Interior was considered and directions were given for the information to be supplied. A letter was considered from Dr. J. Niven, medical officer of health of Manchester, forwarding a copy of a resolution passed by the local supervising authority for that city as to the taking and recording of temperature. The Board decided that Dr. Niven be informed that the matter will be considered on the revision of the rules which is about to take place. A letter was considered from the Birkenhead Medical Society suggesting an amendment of Section 1 (2) of the Midwives Act, 1902, so as to prevent uncertified women holding themselves out as "emergency" women and practising as midwives with impunity. The Board decided that the Birkenhead Medical Society be informed that the suggestion will be borne in mind should an opportunity arise for dealing with it. A letter was considered from a certified midwife suggesting that the Board should issue a badge as the distinguishing mark of a certified midwife. It was decided that the question be referred to the Standing Committee for consideration and report. A letter was read from the clerk of the Cheshire county council reporting a certified midwife for an infringement of Section 1 (4) of the Midwives Act, 1902, and calling the attention of the Board to the fact that the Act prescribes no penalty for a breach of this subsection. The Board directed that the local supervising authority be thanked for their communication. Section 1 (4) reads as follows: "No woman certified under this Act shall employ an uncertified person as her substitute." Letters were considered from Dr. A. F. Whitwell of Shrewsbury, claiming a fee of 1 guinea for information given in the case of a certain midwife. The Board decided that a fee of 1 guinea be paid to Dr. Whitwell without prejudice to the action of the Board in any similar case arising thereafter.

THE late Dr. M. Krönlein, professor of surgery at the University of Zürich, has bequeathed a sum of £12,000 to build a surgical ward for children, £2000 to the pension fund of university professors, and several other sums of £400 each to various other charitable university institutions.

A COUNTY MEDICAL OFFICER FOR WEST SUSSEX.—The West Sussex county council at its meeting on Nov. 25th decided to appoint a county medical officer of health at a salary of £500 per annum with travelling and clerical and other out-of-pocket expenses. The recommendation of the public health committee was that the salary should be £600 per annum with the same additions, but the council decided on the smaller sum. It was explained at the meeting that the appointment was made in accordance with the provisions of the Housing and Town Planning Act, and a general order of the Local Government Board prescribing certain duties to be performed by the county medical officer of health; but although it was quite clear that the officer was necessarily responsible for the inspection of school children it was physically impossible for him to carry out those duties and the council had no intention of interfering with the duties of the present school medical officer.

DEATH OF MR. TREGENNA BIDDULPH GOSS.—Mr. T. B. Goss died at his residence, 1, The Circus, Bath, on Nov. 21st, in his seventy-fourth year. The deceased received his medical education at the Middlesex and Westminster Hospitals, and qualified M.R.C.S. Eng. and L.S.A. in 1863 and 1864 respectively. Mr. Goss shortly afterwards commenced practice in Bath, where he soon became very popular. He held several appointments; he was medical officer to the Royal School for Officers' Daughters, Lansdown; to Partis College, Weston; and for many years he was honorary surgeon to the Eastern Dispensary, Bath. From 1871 until 1908 he was medical officer to the Bath Post Office. Mr. Goss was a staunch Churchman, and for several years was sidesman at Walcot Church. He was also a prominent Freemason. By his death Bath has lost one of her oldest and most respected members of the medical profession. The funeral took place at Locksbrook Cemetery, Bath, on Nov. 25th. In accordance with the wishes of the deceased, the body was previously cremated at Woking.

SALE OF WAX ANATOMICAL MODELS.—A number of wax anatomical models were sold by Mr. J. C. Stevens at his auction rooms, King-street, Covent Garden, London, on Nov. 25th, by the order of the trustees of a deceased medical man. They were the personal work of the late M. L. Loreau, préparateur to the Salpêtrière and Bicêtre Hospital, Paris, and "considered by experts to be the finest in existence." All were mounted in glazed walnut cases, and the original cost was stated to have been nearly £500. They comprised models of the brain as a whole and various sections of the base of the brain, of the spinal cord with its membranes, ganglia, &c., the nervous and vascular supply of the teeth, and models showing the glandular and muscular structure of the lower jaw. One half-length model represented various hernia in the male. A case of specimens, comprising sets of fœtal, deciduous, and permanent teeth, the antrum of Highmore, the inferior dental canal, edentulous jaws, &c., was included. The total sum realised was £27 7*s*.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Nov. 18th. There were present Dr. F. de Havilland Hall (in the chair), Dr. M. Greenwood, Dr. M. G. Biggs, Dr. F. J. Allan, Dr. F. C. Martley, Dr. J. Pickett, Dr. J. W. Hunt, Dr. H. A. Sansom, Dr. W. Knowsley Sibley, Mr. Edward Bartlett, Mr. J. Brindley James, Mr. F. S. Edwards, Mr. Frederick Wallace, and Dr. J. B. Ball. The records of the business for the month of October were exceptionally good, showing a considerable margin in favour of the funds. The sickness experienced has been unusually light, and there is no doubt that 1910 will add a considerable sum to the already large financial reserves of the society. A very good feature of the

business is the large number of members who avail themselves of the facilities offered by recent alterations in the rules to increase the amount of their sickness benefits. Prospectuses and all further particulars on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

UNIVERSITY OF LONDON: GENERAL ELECTION.—CANDIDATURE OF SIR VICTOR HORSLEY.—At a meeting of the Liberal Association of the University of London held on Nov. 28th, Sir Thomas Barlow being in the chair, Sir Victor Horsley, F.R.S., was unanimously adopted as the Liberal candidate. The nomination will be held at the University on Saturday, Dec. 3rd, at 12 noon, and the polling begins on Monday, Dec. 5th, at 8 A.M., and continues till Friday, Dec. 9th, at 4 P.M.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Report on Unqualified Practice.

THE report founded on the Local Government Board inquiry into the extent of the practice of medicine and surgery by unqualified persons has been issued in the form of a small Blue-book. The information embodied in it has been supplied by medical officers of health. The Blue-book throws a lurid light on the evils arising from unqualified practice.

The Dissolution.

Parliament was prorogued, and afterwards dissolved, on Monday, Nov. 28th. The new Parliament after the General Election will assemble on Jan. 31st, 1911.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 23RD.

The Superannuation of Asylum Officers.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether, in the event of any officer of an asylum, to which the Superannuation Act of last session applied, believing himself to be prejudiced in regard either to his right to a superannuation allowance, or as to the amount thereof, he would be prepared to receive and determine an appeal in accordance with Section 15 of the Act.—Mr. CHURCHILL wrote in reply: I am about to take the opinion of the law officers of the Crown on several points which have arisen under Section 15 of the Asylum Officers' Superannuation Act, and I therefore think it would be better to defer answering this question for the present.

THURSDAY, NOV. 24TH.

A Death from Anthrax.

Mr. JOWETT asked the Secretary of State for the Home Department whether his attention had been called to the death of John Beauland, who recently contracted anthrax at the works of Messrs. J. E. Addy and Company; and whether he would examine the depositions of evidence given at the subsequent inquest.—Mr. CHURCHILL answered: I have received reports of this case, from which it appears that the requirements of the regulations which apply to the sorting of wool were not adequately observed by the firm. A prosecution of the firm has been directed.

Dust in Wool-combing Factories.

Mr. JOWETT asked the Secretary of State for the Home Department whether the inquiry which he directed to be made last January into the conditions under which the process of raising a stack of wool was carried on and the means of protecting the workers in wool-combing factories against dust had been made, and, if so, who conducted the inquiry; and what was the nature of the report.—Mr. CHURCHILL replied: Inquiries have been made by the factory inspectors in the districts concerned at all the works which are under the wool-combing regulations as to the conditions under which the process of raising a stack or blending is carried on and the means for protecting workers against dust. The reports which have been received point to the need of steps being taken to safeguard the workers and show that in some works satisfactory measures had already been adopted, such as the use of a steam jet for keeping down the dust and exclusion of workers until the dust is settled, or the provision of exhaust ventilation. Before taking action the chief inspector has thought it desirable to consult the Bradford Anthrax Investigation Board, and it is hoped that its reply will be received very shortly.

BOOKS, ETC., RECEIVED.

LIPPINCOTT (J. B.) COMPANY, Philadelphia and London.

Genito-Urinary Surgery and Venereal Diseases. By J. William White, M.D., and Edward Martin, M.D. Ninth edition. Price 21*s.* net.

Births, Marriages, and Deaths.

BIRTHS.

ALCOCK.—On Nov. 26th, at 22, Devonshire-street, W., the wife of N. H. Alcock, M.D., D.Sc., of a daughter.

MITCHELL.—On Nov. 25th, at Birdsgrove, Woking, the wife of Howard V. Mitchell, M.R.C.S., L.R.C.P., of Clacton-on-Sea, of a daughter.

WHYTE.—On Nov. 28th, at Swatow, China, to Dr. and Mrs. G. Duncan Whyte, a daughter.

MARRIAGES.

COX—WOOLFORD.—On Nov. 1st, at Great Marlow, Bucks, Stafford Mouritz Cox, M.D. T.C.D., to Sophia Woolford, daughter of the late William Woolford, of London.

DREW—MARSHALL.—On Nov. 18th, at Bolton, Lancs., John Harmer Drew, M.D., B.S. Lond., M.R.C.S., L.R.C.P., of Plymouth, son of the late G. F. A. Drew, D.I.G. R.N., to Ada Georgiana, fourth daughter of the late Cornelius Marshall and of Mrs. Marshall of High Bank, Bolton.

MIDDLEBROOKE—WRIGHT.—At St. Chad's, Longsdon, on Nov. 24th, by the Rev. W. Langworthy, of Foston, Herbert Edwin Middlebrooke, of Long Bennington, Grantham, to Mary Ethelwyn, eldest daughter of Robert Wright, J.P., of Leek, Staffs.

STEWART—FRANKS.—On Nov. 26th, at St. Marylebone Parish Church, by the Rev. W. D. Morrison, LL.D., Rector of the Parish, Purves Stewart, M.D., F.R.C.P., of 94, Harley-street, London, W., to Elizabeth Phipps Franks, daughter of the late William Franks, Esq., of Liverpool.

DEATHS.

BRIEN.—On Nov. 24th, suddenly, at Rockferry, Cheshire, Edward Henry Brien, M.D., aged 47 years.

FORRESTER.—On Nov. 25th, at Bournemouth, Charles Carmichael Forrester, M.B., C.M., D.P.H. (late of the Ministry of the Interior, Egypt), fourth son of the late William Forrester, of Arngibbon, Perthshire.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AN AMUSING PROPOSITION.

THE following communication has been received by a well-known medical agent; no word from us is needed to accentuate its humour:—

DEAR SIR,—With reference to your advt. in THE LANCET of this week, I have pleasure in herewith replying to same. I see that you are willing to accept a partnership, and I herewith give you brief particulars of my proposition. I have discovered a cure for the most prevalent of the venereal diseases, and I am desirous of exploiting same. I have a medical and surgical knowledge, but have not graduated and have no degrees, and must therefore have a fully qualified medical practitioner at the head of the medical section. The salary would be between £500 and £1000 per annum, and in accordance with the increase of patients, could be materially increased. The *demand* for this is *enormous*, and as my treatment only takes from 1-2 months to effect a permanent cure (whereas all other methods take 2 years), there is practically a monopoly before it. I have studied minutely the awful conditions and results brought about by this terrible scourge, and apart from any pecuniary motives, I am most anxious to exploit this, if only for the purpose of removing this dread taint from humanity, and so make life for some of the sufferers worth living. I shall be glad to go further into the matter and give you further particulars at an interview, and should be glad if you will make an appointment either by 'phone or letter. Thanking you in advance."

We are certain that this letter was written in absolute good faith, the writer believing that he was enlisting the services of the medical agent in the matter of a professional transaction.

SUPERSTITIOUS REMEDIES.

To the Editor of THE LANCET.

SIR,—With regard to the curious fact that the Welsh word *eryrod* means "shingles" as well as "eagles," will you allow me to point out that the Welsh-English Dictionary of Dr. Wm. Owen Pughe (second edition, 1832) gives the following definition: "Eryri, *s.f.* (eryr)—What is precipitated or thrown out violently, an irruption; the shingles; called also eryr and eryrod." Spurrell (third edition, 1866) gives: "Shingle—Math o grugdardd," which translated means "shingle—a kind of pustule." Richards (fourth edition, 1839) gives no definitive meaning, merely saying, "Eryr, yr eryr, or eryri, or eryrod, *s.f.*—A disease called the shingles." Although there is just a hint in Pughe's definition as to why the word is applied to the disease shingles, none of these dictionaries clear up the question raised by your correspondent as to how this use of the word came about. Hoblyn, it may be mentioned, gives as the probable derivation of the word "shingles" the Latin *cingulum*, a girdle (so-called from the situation of the disease on the trunk of the body).

One of the daily papers, in quoting from THE LANCET the original paragraph, drags in, a little unkindly perhaps, the Salisburian taunt—"the Celtic Fringe." Superstitiousness is not confined to any specific parts of the British Isles. The person who shrinks from passing beneath an upstanding ladder we rub shoulders with every day in the London streets; and the Devil-scaring horse-shoe, is it not gravely installed in many an English home? A fortnight back a lady seating herself at table in certain tea-rooms at Richmond withdrew from her muff a lump of coal which she explained she had that morning picked up in the roadway "for luck." She further volunteered the statement that a little time previously while walking along a Kensington street she saw a lump of coal on the road, and while she was looking at it a carriage stopped and a lady alighted and straightway picked up the piece of coal, asking at the same time the pedestrian why she had not appropriated it. "I thought it rather large," was the reply. "The larger the lump, the greater the luck," rejoined the lady as she re-entered the carriage proud in the possession of her talismanic treasure.

Absurd as are these things, there is an aspect of credulity to which even they must knock under—namely, that unbounded gullibility which allows in this year of grace One Thousand Nine Hundred and Ten the quack to thrive as he has never thriven before—a species of asininity, again, not absolutely peculiar to the "Celtic Fringe."

I am, Sir, yours faithfully,

Stoke Newington, Nov. 21st, 1910. WM. ROBERTS.

ERECTING A BED IN A BALCONY.

COUNSEL recently moved in the Chancery Division, before Mr. Justice Warrington, for an injunction to restrain a gentleman living in a flat at Hove from placing a canvas erection or screen in the balcony of his flat and using it as a sleeping place. Mrs. Chandless, the plaintiff, was an elderly lady who had purchased her house, No. 10, King's-gardens, Hove, for £10,000, and Mr. Ford, the defendant, had rented a flat on the first floor of No. 9, for which he paid 10 guineas per week. Having been ordered by his medical adviser to live as much in the open air as possible, the plaintiff had a canvas structure in the nature of a tent or screen put up in his balcony to shelter a bed, in which he admitted that he slept at nights, although in his affidavit he denied "using the balcony as a bedroom," from which it may be inferred that he did not use it as a dressing-room. The plaintiff was apprehensive, however, lest he should be suffering from "consumption or some infectious disease," and it was stated that she endeavoured to protect herself by putting up a partition or screen outside her windows which she caused to be sprayed periodically with disinfectants. In her affidavit she stated that she had seen the bed on the balcony and a nurse sitting at a table with a lamp, and had also seen the gentleman in his bed, and had heard him give directions as to when he should be called. In asking for an injunction to prevent the described use of the balcony, counsel relied upon a covenant relating to the occupation of the flats, which, he said, were not to be used so as to cause offence or damage to other occupants or so as to interfere with the pleasurable enjoyment of their property. After hearing arguments on both sides, his lordship held that as the defendant was not suffering from any infectious disease he had not done anything to which a reasonable person could object, and he consequently refused to grant the injunction asked for. In comment, it may be said that the question whether the defendant might obtain sufficient fresh air without resorting to the balcony at night should be a matter for the decision of his medical attendant, from whom no evidence was apparently put forward at the hearing of the motion. The alarm of the plaintiff on the score of possible infection was, of course, groundless, but it may fairly be pointed out that, apart from this and from the applicability of the covenant referred to, the use in the manner described of the balcony of a flat on the first floor in what house agents would term "a first-class residential neighbourhood" is unusual and not unlikely to be resented by those living in other flats in the same building or in adjoining houses, or, in the case of a street, by residents on the opposite side.

WANTED—SUGGESTIONS FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—Could any of your correspondents advise me as to the safest anthelmintic to give a woman, nearly five months pregnant, who is suffering from tape worm? I am, Sir, yours faithfully,

Nov. 28th, 1910. TÆNIA.

HEALTH AND HOSPITALS IN GRENADA.

ACCORDING to the report of the Governor of Grenada on the annual Blue-book of the Colony, the population at present consists of 35,463 males and 38,697 females—total, 74,160. The birth-rate per 1000 of the mean estimated population in 1909 was 34·76, a very low figure for Grenada; and the death-rate was 18·82, also very low. Although the health of parts of the colony was disturbed by outbreaks of enteric fever and influenza, the death-roll of the year was small. The first-mentioned disease was practically confined to the Carriacou and St. George's districts—66 cases with 9 deaths occurring in the former, and 14 cases with 1 death in the latter. In the past Grenada has been little troubled with this disease. Influenza was epidemic towards the end of the year, and its effects seem to have been most felt in St. Andrew's, where 26 of the 39 deaths attributed to it were recorded. 872 patients were treated during the year in the Colony Hospital, of whom 495 were discharged cured, 247 relieved, and 44 died. In the out-patient department there were 1575 attendances given. The number treated in the Yaws Hospital again showed a marked increase, being 420, as compared with 266 in 1908, and the admissions were 361, as against 207. Of these, 339 were discharged cured. There was one death, its cause being general tuberculosis. In St. Andrew's District Hospital 159 patients were treated, 128 discharged cured, and 10 relieved. At the District Dispensary attached to this institution 9951 prescriptions were compounded. The free prescriptions have increased from 1857 in 1902 to 6402 in 1909. In the Carriacou District Hospital 278 patients were under treatment, of whom 203 were discharged as cured, 35 as relieved, 5 as not improved, and 12 died.

The rainfall in 1909 was heavy, but was fairly evenly distributed over the year. At the Richmond Hill Observation Station, in the south of the island, 80·54 inches were received, as compared with 68·44 in 1908, while at Plaisance, an estate in the mountains, no less than 212 inches were recorded. In Carriacou 67 inches were registered, and on three occasions there was an abnormal downpour. On April 22nd, in the "dry" season, 3½ inches fell there; on August 21st 5 inches fell in three hours, and on Sept. 16th 3 inches in less than an hour.

A DISCLAIMER.

THE article by Mr. John McElroy, published in THE LANCET of Nov. 12th, having been largely copied by the lay press, the author has written to say that some remarks which might be construed to mean that information had been given by him to a lay paper are incorrect. He regrets that such an impression should be conveyed to his medical brethren, and desires to point out that he had absolutely no knowledge of the copying until his attention was called to it.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—Everybody knows the usual formula for converting degrees Centigrade into degrees Fahrenheit—viz., divide by 5, multiply by 9, and add 32. The following alternative method may be found easier to perform mentally as the figures can be more easily retained in the memory—viz., multiply by 2, deduct one-tenth of the product, and add 32. Example (*a*), 30° C. = 86° F. Method: 30 × 2 = 60. 60 − 6 = 54. 54 + 32 = 86. Example (*b*), 37° C. = 98·6° F. Method: 37 × 2 = 74. 74 − 7·4 = 66·6. 66·6 + 32 = 98·6. Example (*c*), 40° C. = 104° F. Method: 40 × 2 = 80. 80 − 8 = 72. 72 + 32 = 104.

I am, Sir, yours faithfully,

London, Nov. 17th, 1910. F.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Dec. 8th and 9th (London, Guildhall).—Conference of Health-promoting Institutions and Fifth Annual General Meeting of the National League for Physical Education and Improvement.
,, 19th–22nd (Rome).—Twentieth Congress of Internal Medicine.

In 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
April 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
,, (Turin).—International Congress of Pathology.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 24th–30th (Rome).—International Congress on Tuberculosis.
,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Genoa).—International Exhibition of Marine Hygiene.

In 1912:—

July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.

In 1913:—

(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.

In 1915:—

(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Albert Carless, James Galloway): at 8 P.M.

Cases and Specimens.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Dilatation of the Heart and Heart Strain (resumed by Dr. W. Collier (Oxford), followed by Dr. S. West, Dr. A. Morison, Dr. F. J. Poynton, Sir John Broadbent, Dr. C. W. Chapman, Dr. F. P. Weber, and Dr. L. Guthrie).

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Clinical and Pathological Evening.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

WEDNESDAY.—5 P.M., Sir Alfred P. Gould, K.C.V.O.: Cancer. (Bradshaw Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Dr. W. W. H. Tate: The Significance of Pain as a Symptom of Disease of the Pelvic Organs.
TUESDAY.—4 P.M., Dr. J. Collier: Clinique (Medical). 5.15 P.M., Lecture:—Dr. H. Campbell: The Treatment of Bronchitis in the Aged and Feeble.
WEDNESDAY.—4 P.M., Mr. B. M. White: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D'Oyle Grange: Infective Arthritis.
THURSDAY.—4 P.M., Dr. R. Wells: Clinique (Medical). 5.15 P.M., Lecture:—Mr. S. Hastings: The Results of Nasal Obstruction.
FRIDAY.—4 P.M., Dr. G. Thompson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Surgical Treatment of Hæmorrhage from Gastric and Duodenal Ulcer.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Pneumonia.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Bernstein.
FRIDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Mr. J. Cantlie: Applied Anatomy of the Abdomen.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting). 4.30 P.M., Special Demonstration:—Dr. A. J. Whiting: Selected Medical Cases.
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Dr. A. G. Auld: The Diaphragm in Health and Disease.
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. James: The Signs and Treatment of Dental Caries.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Fenton: The Weak Heart.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. L. Paton: Optic Neuritis.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Holmes: Cerebral Tumour.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: External and Middle Ear.
FRIDAY.—3.45 P.M., Lecture:—Dr. Abercrombie: Clinical Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Bullous and Vesicular Eruptions—I., Urticaria; II., Pemphigus; III., Pompholyx; IV., Varicella.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. S. Bishop: Appendicitis. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (7th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (8th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (10th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

The Bradshaw Lecture

ON

CANCER.

Delivered at the Royal College of Surgeons of England on Wednesday, Dec. 7th, 1910,

BY SIR ALFRED PEARCE GOULD, K.C.V.O., M.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO THE MIDDLESEX HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—In 1884 the late Sir William Savory chose as the subject of the third Bradshaw lecture the Pathology of Cancer. He pronounced the cancer cell to be an "embryonic" or "rudimentary" form of cell, possessing great powers of multiplication and of endurance, but differing from true embryonic cells in its lack of power of differentiation. And then he used these remarkable words:—

> And while tumours of the most innocent type touch, and indeed pass into, natural structures, the most malignant touch, if they do not actually pass into, the class of parasites. ..... The interval between the worst kind of cancer and a parasite must be a very narrow one.

He suggested that the experiments on cancer grafting had probably failed owing to the "crude conditions under which they have been performed." He concluded thus:—

> Before we shall ever be able to answer the question, Why or how do tumours form? it seems to me we must be able to solve the problem of normal growth and development, and to answer the question why or how it is that these continue up to a certain point and then suddenly cease.

For the succeeding 19 years the Bradshaw Lecturers dealt with other subjects, but in 1903 Sir Henry Morris gave a learned review of the many theories that had been advanced to explain the origin and nature of cancer, and specially discussed two theories: the microbic or parasitic theory, which he held to be "non-proven," and Cohnheim's theory of "cancer matrices," ante-natal and post-natal. This theory he strongly supported as explaining all the facts of the disease then known, and he confidently foretold for it a speedy acceptance by all pathologists.

Two years later, in 1905, you, Mr. President, announced, as the title of your Bradshaw lecture, "Carcinoma is a Parasitic Disease," and stated:—

> That the carcinoma cell is an independent organism, like many a protozoon; that it lives a life which is wholly independent and proper to itself; and that it lives as a parasite in the body of the animal which is affected with carcinoma, deriving its nourishment from the host, and having nothing to pay the host for the sustenance of which it robs him.

You shrank from accepting Hauser's suggestion that the protozoal cells of cancer are derived or descended from the living cells of the host, and asserted rather that "the parasite is introduced into the body from without."

It is needless to say that each of these divergent theories has been discussed from the standpoint of a very wide and accurate knowledge of the subject, and that each in turn has been supported with extraordinary ability and with the enthusiasm of a strong personal belief. For me to attempt another review of the same facts and arguments would be to act the disastrous part of Phaeton, and yet I propose, Sir, to raise once again the great problem of the nature of cancer, not because I can read aright the riddle solved so differently, and with such mutual destructiveness, by my predecessors, but because within the last few years the workers in our cancer laboratories have added so much to our store of knowledge that it seems wise to see how far the new facts support or refute former conclusions. We are like children putting together a dissected picture, we slowly look over and often vainly try to fit together the irregular pieces of the puzzle, but gradually order comes there and there out of chaos, and as piece after piece finds its proper setting the picture grows until the fitting in of the final fragment reveals the whole design.

DEVELOPMENT OF CANCER RESEARCH.

In addition to the influence of the general progress of biological knowledge, two discoveries have caused a great development in cancer research: the proof that cancer can be transferred from animal to animal, and the demonstration of the influence of radio-active bodies upon cell growth. Scientific workers have devoted themselves to the solution of the problem of cancer with new courage and more confident hope since they saw that it could be submitted to that experimental method which has so often dissipated the darkness of ignorance. All over the civilised world cancer research laboratories, more or less exclusively devoted to this quest, have been founded, and never before have the efforts of scientific men been so largely centred in the study of any one disease. Highly gifted investigators are devoting themselves with praiseworthy devotion to the study of the internal structure and arrangement of cancer cells, to a search for the forms and evidences of the presence of an invading organism, to a close scrutiny of all that takes place in the artificial transmission of the disease from animal to animal, and to the investigation of the various abstruse problems in bio-chemistry and physics that it is hoped may aid in the discovery of the nature and cause of cancer. This College, in conjunction with our sister in Pall Mall, by the initiation, control, and housing of the Imperial Cancer Fund, has taken a very prominent part in this movement, and it is a matter of great satisfaction that the researches carried out in our laboratory are universally recognised as having been of fundamental importance. We gladly recognise that all the success which has attended, and may hereafter attend, the labours of Dr. Bashford and his distinguished associates is not due to the association with these Royal Colleges, nor to the sources from which the fund has been collected, but to the ability, the wide knowledge, the patience, and the honesty that are associated with the laborious industry of the workers. It is not my purpose to give a detailed account of the latest results of cancer research, but rather briefly to enumerate some of them, and to see whether and how far they enable us to unravel what has hitherto been a tangled skein.

INCIDENCE OF CANCER IN MAN AND ANIMALS.

It is now known that *cancer occurs in all races of men.* Wherever adequate investigations have been made cancer has been found, and the fuller our knowledge of any people the ampler is the evidence of the presence of cancer among them. We are unable, therefore, to attribute the disease directly to the influence of race, of climate, of diet, of occupation, of soil, of the subtler accidents of civilisation, or to any of the associated and complex conditions that may be summarised as "environment." Not that these factors are without influence. Certain occupations are assuredly attended with peculiar liability to cancer; I need only mention chimney sweepers and workers in X rays, tar, and paraffin; and the beneficent effect of circumcision in greatly diminishing the incidence of epithelioma of the penis, and the pernicious influence of the use of the kangri, show us how the disease may be affected by social customs. It is clear, however, that we may not regard any of these conditions as the essential cause of cancer, for the disease occurs in their absence, and we must carefully guard against confusing subsidiary, accelerating, predisposing factors with the inevitable, constant cause of the disease.

Human statistics cannot be relied upon to substantiate or define the influence of race. Dr. Bashford has been at great pains to point out the imperfect character of all statistics of cancer incidence, and he has clearly shown that the proportion of cancer reported among different nationalities is at present only a measure of the value of the material submitted to examination, and must not be taken as a true picture of the actual frequency of cancer. Only as care in diagnosis, in pathological examination, and in records improves and becomes uniform in all races of men, shall we be able to state with precision what influence race, among many other factors, has upon the incidence of cancer. The experimental study of cancer has, however, shown that we must not assume that all races of men are equally liable to cancer. Very early in the investigations into the inoculability of mouse cancer

it was realised that there were serious discrepancies in the results obtained by different expert workers. Some of these discrepancies were caused by differences of technique, others by inattention to the age of the mice used for the experiments, and others again to the particular tumour experimented with. Chiefly owing to the work of Dr. Bashford these causes of variation in the results obtained have been recognised and eliminated, and the influence of race has thereby been demonstrated. Such facts as these have come to light. Haaland found that a certain tumour grew on inoculation in nearly 100 per cent. of Berlin mice, in 24 per cent. only of Hamburg mice, and failed altogether to grow in Christiania mice. Loeb has a sarcoma which was readily propagated in white rats, and could not be inoculated into coloured rats. Tyzzer has a carcinoma found in a Japanese waltzing mouse, which he can transplant successfully in practically 100 per cent. of this particular family of mice, but which altogether fails to grow when inoculated into common mice. On the other hand, Jensen's tumour, which grows readily in common mice, cannot be inoculated with success into the Japanese waltzing mice. In hybrids resulting from the crossing of common white mice and Japanese waltzing mice, the Japanese tumour grows as uniformly and even more rapidly than in the pure Japanese mice, but in the second and third generations of the offspring of these hybrids the Japanese tumour cannot be inoculated at all. In his earliest inoculations of Jensen's tumour, Bashford found it impossible to succeed with blue mice, while he obtained 25 per cent. of success with other tame mice. He also relates that a tumour sent to him by Dr. Michaelis of Berlin was transplanted into 19 Berlin mice, with the result that nine tumours grew, but only one small tumour developed in 182 tame London mice similarly inoculated. It is, of course, most important to keep clearly before one's mind the difference between the liability to occurrence of sporadic cancer in an individual or animal, and the susceptibility of such an individual or animal to the successful inoculation with cancer transferred from another. Such facts as I have just mentioned, however, make it imperative upon us, while recognising the presence of cancer throughout the human race, to keep a mind open to receive a demonstration, should it come, of the influence of race upon the incidence of cancer, apart from all accidental and accessory conditions.

Passing now from this first fact—that cancer is a disease of man wherever and however he lives—I would next remind you that we have recently learnt that *cancer is a disease that occurs in all vertebrate animals.* It is not limited to man, nor even to man and primates, nor even to the great family of the mammalia; it has been proved to occur in birds, reptiles, and fishes. The disease, as met with in the lower vertebrates, is not a similar disease, but veritable cancer, with the same histological characteristics and with those special biological features that we find in man—the uninterrupted growth, the power of infiltration, and the formation of metastases. The importance of this demonstration is enormous. It dissipates at once all those theories which would find the cause of cancer in any condition peculiar to man; we have to seek it in some influence which man shares with all other vertebrates. When we reflect that there is no known instance of an external infective agent or organism which spontaneously attacks and produces its characteristic pathological effects in all vertebrata, or in all the varying physical conditions of environment in which cancer is found, the parasitic theory of cancer fails even to be a satisfactory "working hypothesis." We can only adopt it, if the fact is demonstrated and Koch's conditions of proof are fulfilled; and such a demonstration is certainly not forthcoming.

That cancer can be transferred from host to host is now attested by thousands of successful experiments upon mice, rats, and dogs. Four facts have come to light during these inoculation experiments which are important to bear in mind. In the first place, the successful grafting of cancer from animal to animal is far more difficult to accomplish than is the inoculation of microbic disease. In the second place, it has been found that it is always difficult to succeed in the primary grafting experiments of a sporadic mouse tumour into another mouse, or in the first graftings of a tumour upon a fresh family of mice. In the third place, as I have already mentioned, it has been found that when allowance has been made for these variations the success of grafting experiments may vary considerably in different races or families of mice. And then towering above these lesser facts is the greater, all-important one, that *cancer cannot be transferred to an animal of another species.* Cancer of a mouse is readily transferred to other mice, but it cannot be grafted upon a rat, or upon any other animal of another species. The same holds true of cancer of the rat and dog, and in this specificity of cancer we see the cause of failure of all experiments to graft the human disease upon lower animals. These failures were not due, as Savory suggested, to the "crude methods" employed, but to the working of a biological law.

The fact that an inoculable disease is specific in the sense that it cannot be transferred from species to species surely must be one of great importance in any consideration of its nature, for the grouping of animals into species is not artificial. The differences that we recognise between species have a greater element of permanence than those between varieties; the offspring of crossed varieties are fertile, while the hybrids of crossed species are almost invariably infertile; the number of chromosomes in somatic cells differs widely, but it is constant for every species. Difficult, therefore, as it may be to express the distinguishing limitations of a species in terms which will satisfy the exacting criticisms of modern schools of biologists, all agree that the word connotes a reality, that it indicates an important step in the path of evolution, and that the limits between species are true landmarks. The enormously wide range of the incidence of cancer, the uniformity of its biological characters, and its specific inoculability are a triad of facts unique in pathology and of tremendous significance. Apart from many minor considerations, I venture to submit that they are inconsistent with what we know of infective or parasitic diseases. They, too, are no doubt "specific," but the specificity is attached to the disease, and neither to the animal nor to the tissue in which it occurs. The tubercle bacillus leads to the same disease in the guinea-pig as in the man from whom the virus may have been taken. The minute anatomy of tubercle is the same in whatever part or tissue of the body it arises; it does not vary with its primary site, as is constantly the case in cancer. Cancer is distinguished from all infective and parasitic diseases by the fact that the cellular parentage of a malignant growth is always definitely marked, and that whether it originates in squamous, columnar, or spheroidal epithelium, in endothelium, or in any of the forms of connective tissue cells, it retains throughout its whole life, and wherever found, characteristic features of its parent cell. Parasitic diseases are anatomically and etiologically specific—specific in their structure and cause; cancer is specific not in structure, perhaps not in cause, but in the physiological character of its cells.

THE CANCER CELL.

The essential part of every cancerous growth is the living cancer cell! The cell, whether of carcinoma or sarcoma, is the one essential part, that which contains within itself all the potentialities of the whole of cancer. While it lives as a cell, the cancer is living, when it dies as a cell, it is impossible to find or develop or excite any of the parts, or agencies, or faculties of a cancer. By no one has the demonstration of this fact been carried so far, or made so indubitable, as by Bashford and his fellow-workers in our laboratories. Their investigations into what takes place in the "early stages" of successful transference of a cancer from mouse to mouse have revealed, that in the tiniest practicable graft, all the introduced stroma, and many of the centrally placed cancer cells die, but that the cells, or some of them, in the periphery of the graft live, do not undergo degenerative changes, and after a few days—usually about four—excite the formation from the fibroblasts of the host, of a new supporting and vascular stroma, and themselves show the changes indicative of cell division. The parenchyma of the tumour, which ultimately may grow to a huge size, all develops directly from those cancer cells of the graft which were able to withstand the hurtful influences of the process of grafting. While it is possible to transfer cancer from mouse to mouse so long as care is taken to introduce living cancer cells in the graft, it is impossible to do this when the cancer cells are destroyed by pounding in a mortar, or their vitality has been injured, as by the influence of heat. Indeed, Schwann's

great doctrine of "*omnis cellulae cellula*" is peculiarly true of cancer.

On the other hand, it has been equally clearly shown of inoculated infective granulomata that they grow not from the graft but from the connective tissue of the host. This difference between cancer and infective granulomata is of fundamental importance, a veritable *differentia*. The metastases of cancer and of granulomata may be alike in some of their coarser anatomical features, such as their site, but in their nature, in their true biological characters, they are absolutely distinct, with a distinction which is vital and fundamental. If the living cancer cell is the essential part of cancer it is important to know what are its anatomical and physiological characteristics. A study of them demonstrates that the cancer cell is only a variation of a normal cell—it possesses neither in structure nor in powers anything not found in the healthy cell. Let me rapidly mention the established facts about living cancer cells.

First, *they possess a great power of continuous multiplication*. So far as the experiments with Jensen's tumour have gone it seems that the grafting can be carried out with it as successfully now after seven years as at first and that from the small sporadic tumour in the mamma of a mouse a mass of cancer has been grown through an unknown number of mice, amounting to far more than a thousand times the bulk of the original tumour, or even of the original mouse. Bashford has particularly laid stress upon this striking fact, and has spoken of it as a "new" biological fact, but in that I think he has probably exceeded. Certainly in the protozoa such apparently endless multiplication and growth of living cells can be recognised. And when we cast our minds back to the development of the human ovum—a single cell—and remember that from it directly descends the entire mass of cells which form and maintain through his threescore years and ten the full stature of a man, we see a power of cell growth which we need not shrink from comparing with that of a Jensen's cancer cell. But it is particularly noteworthy that in cancer this power of continuous multiplication is spontaneously manifested most often in the cells of an organism that has passed the period of youth and maturity, and has already entered upon the declining phase of life.

The second characteristic feature of the cancer cell is that *it retains the inherited limitations to type* of the cells among which it first appears. The descendants of an epiblastic cancer cell retain, in the main, the features of their early parent—a hypoblastic cancer cell bears its own family likeness, and the sarcoma cell is always a distinctively mesoblastic cell. Even in those remarkable experiences that have been so carefully studied and admirably recorded by Bashford and Haaland, when they observed in a series of transplantations of an undoubted epiblastic cancer of a mouse its gradual conversion, first into a cancer with a richly cellular stroma, then into a "mixed" tumour, and finally into a sarcoma, it is clear that the mesoblastic cancer (sarcoma) thus formed sprang from the connective tissue cells of the hosts, and that its cells are in no sense or degree the lineal descendants of the original cells of the epiblastic cancerous parenchyma.

Thirdly, *cancer cells develop and differentiate but little and irregularly*. Thus in a squamous epithelioma there is great variation in the extent to which keratinisation of the cells occurs, and in some cancers we see such departures from type as a change from squamous to columnar cells and from spheroidal to columnar cells, or *vice versâ*; the differentiation of a mammary cancer may be into acinous or glandular carcinoma or into a combination of the two. This variation in growth has been best observed in the experimental work in laboratories, where the opportunities of studying the same strain of tumour in many succeeding stages of its growth and through many hosts afford scope for observation such as can never be found in human pathology.

The development of the cancer cell is neither purposeful nor effective. In glandular carcinoma no regular grouping of acini around primary ductlets is found, nor does the cell metabolism issue in useful secretion. In a squamous carcinoma no impermeable protective covering is formed, and in a sarcoma no useful fibrous bands or aponeuroses, no attached and functional muscles, no perfectly constructed and useful bone is formed. In cancer there is cell multiplication in exaggerated degree, but a lack of adaptation to the many and varied needs of the organism. The cancer cell shows no new faculty or endowment, no power of "rising on its dead self"; it is a less highly endowed cell than its physiological parent. Then, again, *cancer cells exhibit periodicity in their growth*. Bashford has found that a mouse tumour has its period of active growth succeeded by one of less activity, and that the success of artificial transference of the disease to other mice rises and falls with this wavelike activity of the tumour, and he has found that this periodic activity is transmitted to the tumours which arise from the grafts—that it is an inherent or inherited property. Similar variations in the rate of growth and activity of cancer are also seen in the human subject, and we see periodic activity in metastases—periodic activity in their occurrence as well as in their growth. We must not look upon such variations as due, of necessity, to a change in the resisting forces of the patient; they are probably due to the inherent periodic growth of cancer. Physiological periodicity of cell growth is, of course, well recognised; I need only mention such examples as the sexual periodicity in animals and especially in the human female, the periodic growth of young animals, the periodic growth of hair, and the periodicity in the life-history of salmon, and the periodic variation in the colour of the fur and feathers of many mammals and birds.

The study of the form of cancer cells and the attempt to find in it some index of their nature has yielded but little that is positive. The many determined efforts to see within them foreign living forms, whether of bacteria, of protozoa, or of yeasts, have failed. Bacteria may, of course, intrude within a cancer cell, but it was a cancer cell before the intrusion, and we may assert with some confidence to-day that there is no visible evidence of parasitism in the cancer cell. Nor has the hopeful and brilliant study of the mitoses of cancer by Walker, Moore, and Farmer, and their followers lifted the veil. It seemed that the theory that cancer was a gametoid tissue would explain much, or at any rate establish on a firm footing the nature of the disease. But we must regretfully consent to see that hope unfulfilled, and admit that mitosis is no key to the riddle. Quite recently, however, it has been shown by Beckton that all the cells of man, except the keratin cells of squamous epithelium, the cells lining the conducting tubes of the kidney, the cells of unstriped muscle, and the unimpregnated ovum, contain certain granules, which are known as Altmann's granules. While unrecognisable in the protoplasm of the ovum, these granules are seen in the unincubated blastoderm of the egg, and are readily recognised after six hours' incubation. Beckton has found them in mouse embryos of 8 mm. and 12 mm. in length, and in the rat embryo of 30 mm. They appear, therefore, very early indeed in the descendants of the original single ungranulated cell of the ovum. Beckton states that these particular granules are seen in the cells of the stroma of carcinoma, *but not in the cells of the parenchyma*, and while abundant in the protoplasm of inflammatory and granulomatous tissue they are invariably absent from the cells of sarcoma. Beckton examined also 21 mouse tumours sent him by Dr. Bashford, and in 14 of them there were no granules, but in five instances they were present. They are therefore commoner in mouse tumours than in human malignant growths. Should further observations confirm Dr. Beckton he will not only have given us a very useful method of diagnosis, but he will have established a morphological difference between cancer cells and most normal cells. He will also have afforded an anatomical proof that cancer cells are not embryonic cells.

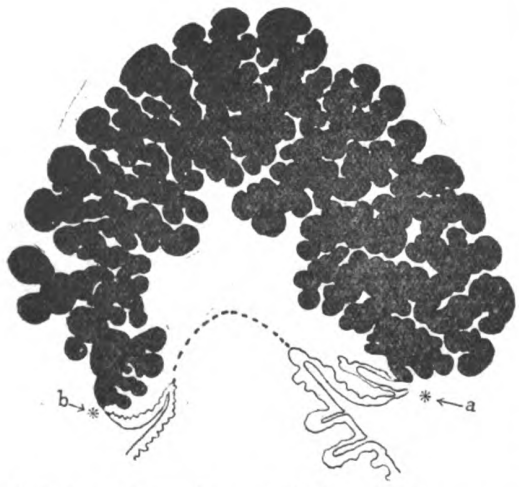
Of the *intracellular metabolism of the cancer cell* we know but little; it seems to beget no toxin, to generate no new substance, and to depart but little from the chemistry of health. And yet we cannot doubt that its special biological characters are inseparably linked with some intracellular chemical peculiarities. We have evidence of this furnished by some very careful spectroscopical observations made by Mr. Mottram in Dr. Lazarus-Barlow's laboratory, by which he has shown that the potassium content of the red corpuscles of cancerous patients is considerably higher than in health, the difference being represented by the figures 1·5 and 3. The sodium content, on the other hand, shows no change. The importance of this observation is enhanced by the further

fact that while the sodium content of all carcinomatous tumours is about the same, the potassium content of primary cancerous growths is higher than that of secondary, and the potassium content of squamous-celled tumours is higher than that of spheroidal celled. Mottram has, therefore, shown that the cancer cell has a chemical coefficient, but it is a modification in degree, and not in kind, of that of the healthy cell. These are the facts at present known about cancer cells as independent entities. We must now look at them as members of a community, and study their relations to neighbouring cells.

First we must notice *the disproportionate growth of the cancer cell.* It bears no relation to the growth, the needs, or the condition of the neighbouring cells and tissues, and, as it often tends to outgrow its stroma, and, by the pressure of its cells, to compress the capillaries, we have in this fact an explanation of the frequent degeneration, fatty and otherwise, of the cancer cells. The hæmorrhage which so frequently occurs in some cancerous growths may also be in part due to the same fact. The disproportionate growth of the cancer cell has been mistaken for evidence of its being an independent organism, but we shall see abundant reason for rejecting this view and for being certain that a cancer cell is an altered body cell.

The pressure caused by the incessant and disproportionate *multiplication of the cancer cells causes not only complicated infoldings of the cancer itself, but flattening and distension of the adjacent soft tissues.* In his second Scientific Report, Dr. Bashford has published drawings of an epithelioma of the lip to show the enormous folding up of the cancerous parenchyma, and that what at first sight appears to be a solid infiltrating growth is really an immensely extended superficial growth, folded up into a ball, filling at first the narrow space it acquired for itself by pressing aside the yielding tissues of the lip and then projecting on the surface. (Fig. 1.)

FIG. 1.



Squamous celled carcinoma of the lower lip in a man. The growth is a folded and crumpled sheet intercalated between the outer and inner surfaces of the lip. Shows folding of skin (*a*) and mucous membrane (*b*) over the margins of the growth, with great lateral displacement of the normal tissues adjoining either margin.

Bormann has shown that the papillæ immediately next the growing edge of an epithelioma of skin or tongue are not exaggerated in size or cell activity, but are compressed and stunted. These observations run right athwart the commonly received notion that as soon as epithelial or other cells have acquired "malignant" properties they burrow deep into the surrounding tissues, and that the similar adjacent cells also show active growth (Fig. 2) and a readiness to participate in the disorder, as if "infected" by the malignant tendency. Unless Bashford's and Ribbert's statements are erroneous, they afford a demonstration that cancer cells in their growth give a qualified obedience to the law which regulates and controls the growth of the normal cells from which they are derived.

But if the first effect of cancer cells upon their neighbours is to compress them, their second and far more important power is to *invade the adjacent tissues.* This power of infiltration, as it is called, or permeation, is so well recognised that I need only mention it. The growth may penetrate even to bone and marrow, and in doing so cells, or groups of living cells, pass into lymphatic or vascular channels, and are carried along by the slowly or swiftly moving stream therein, and may lodge in distant parts and develop into metastases. But they may not do so. Handley's studies of the process of

FIG. 2.

Squamous celled carcinoma of the lower lip in a man. Shows sharp demarcation of the growth from the adjacent skin (*a*) and mucous membrane (*b*). At (*a*) the elongated epithelial papillæ of the skin are displaced by pressure of the growth; they are also being undermined and will be pushed off. At (*c*) the hair follicles already show displacement from pressure.

lymphatic permeation have shown us that the passage of a cancer cell along a lymphatic is attended with great peril to it, the lymphatic endothelium has great power of cancer destruction, and for every cancer embolus that resists it successfully and thrives and multiplies—bursts through the lymphatic wall and develops as a metastasis—many a one falls a prey and dies. The same holds true of the hæmovascular embolisms. These have been studied by Borrel, Haaland, Bashford, Murray, Tyzzer, and others, and the resisting or destructive influence of the vascular endothelium on the cancer cells has been clearly demonstrated. The cancer cell when it wanders from its proper plane or sphere has to fight for its life; normally and in favourable conditions the "odds" are against it, and our post-mortem records bear abundant testimony to the ability of the forces of resistance to these cell intrusions to limit the disease in many cases to the area originally attacked, even up to the death of the patient from the disease. While, therefore, we must not for a moment under-estimate the grave importance of the permeation of cancer and its tendency to develop metastases by the transference of the living cancer cells to distant parts of the organism, we must be careful to regard this in its due proportion and to remember that all infiltration and every metatasis is only accomplished at a period later than the earliest onset of the disease and after the overthrow of very real natural resistance.

In this connexion I would mention that cancer-bearing mice are not a favourable soil for the grafting of other cancerous tumours until the period at which they spontaneously develop metastases. In the earlier stages the resisting forces of the organism can hold at bay the cancer cells whether spontaneously or artificially introduced into the tissues; in later stages either form of inoculation becomes potent. The occurrence of metastases is the resultant of two forces—the vigour of the invading cancer cell and the resistance of the tissues to its development within them. This resistance may be inherited or racial, naturally acquired by age, artificially acquired—as shown by Bashford's experiments with the inoculation of various tissue-extracts—and it may be lessened by the persistent presence of a primary cancerous growth.

A very interesting fact about the influence of the

cancer cell upon its neighbouring cells is its *compelling them to form a supporting and vascular stroma for it*, of a type governed by the cancer cell and not by the stroma-yielding mesoblastic cells. Along with this, however, there is clear evidence that the surrounding cells exert an influence upon the cancer cell; this is shown by its greater vitality and power of multiplication in the young than in the old, by its more active growth in certain races or families of animals, and by its inoculability being limited to animals of the same species. Two other facts are also full of significance: In the experiments in the propagation of mouse cancer it has been shown that when a graft is implanted in a fresh family or race of mice it grows with great difficulty, and that with each generation of grafts the success increases until it often reaches 100 per cent. This must not be confused with the increased virulence of an infective organism that may be produced by passing it through a series of animals, for the virulence of the cancer cell is only raised for the one particular variety of mouse and not for others. It is a subtle influence of the host upon the introduced cancer cell which makes it more congenial to the tissues of the particular variety of mouse. And then we have the remarkable fact that Bashford discovered that in certain cases the repeated inoculation of an epithelial cancer stimulates the mesoblastic tissues of the host so intensely that the stroma becomes proportionately more and more abundant, and more and more richly cellular, while the epithelial growth lessens, until the carcinoma is replaced by a sarcoma. No more surprising, wonderful fact has yet been forthcoming from cancer laboratories than the demonstration of this "transformation" of an epiblastic malignant growth into a mesoblastic cancer, the carcinoma exciting the development of a sarcoma, and thereby being itself destroyed.

What is the meaning of all this? Remember that the escape of epithelial cells into the tissues beneath them is a physiological process. Years ago Dr. Creighton demonstrated it in the case of the breast; he also showed that these permeating epithelial cells were destroyed in the lymphatics. Permeation is not a new power of cancer cells, although it exists in them in an unusual degree. I think we can recognise in the facts I have just mentioned evidence that the cancer cell is not an alien cell; it influences, and is itself influenced by, its neighbours as a normal cell is. The mutual adaptation and mutual influence of the cancer cell and its stroma surely speak of common descent—of blood relationship, if I may use that term. If, now, we attempt to piece together these various facts, what disease picture do they make? When we consider the intimate connexion shown between cancer cells and the cells of the individual, and, perhaps, above all, the artificial conversion of a carcinoma into a sarcoma, we cannot recognise in cancer an independent parasitic growth, protozoal or other. Not only are the necessary evidences of the presence of specific pathogenic microbes absent, but both in broad outline and in particular detail the life-history of cancer is fundamentally different from that of the great host of known bacterial and other invasions. Nor is it possible any longer to see in cancer a reversion to the embryonic type of growth; that, before all else, is orderly, regular, with a long vista of development, differentiation, and functional activity. Cancer is cell life that is disorderly, irregular, with a minimum of development, differentiation, and function. Still less can we find a satisfactory explanation of this great disease in a circumstance so accidental, so trivial, as the sudden awakening into activity of entirely supposititious "embryonic rests."

WHAT IS CANCER?

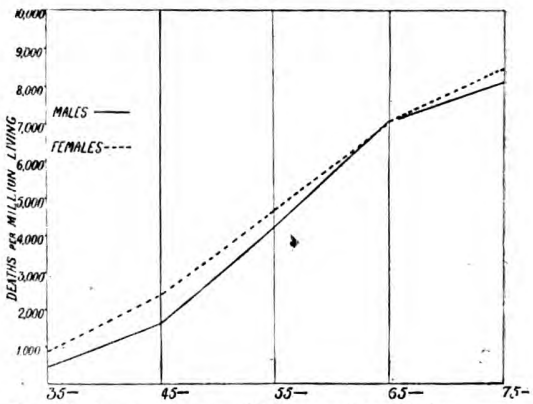
What, then, is cancer? Before answering the question, think of the fertilised human ovum, a single nucleated cell. Picture it dividing into 2, 4, 8, 16, and 32 cells, all similar in size, form, and structure. Trace on these cells as they multiply by division and see them silently range themselves in the three primary embryonic layers—epiblast, mesoblast, and hypoblast, and by that step effect a separation of cells which to our senses appear identical, but whose destiny marks them out as absolutely distinct. Follow on the wonderful drama of development, try to realise the orderliness of it all, the varying differentiation of epithelia, endothelia, and connective tissues. Observe the intimate association of these embryonic layers in the evolution of parts and organs, their perfect coöperation, their mutual dependence. See the rising up here of mesoblast into papillæ, ever clothed with epiblast, and there the down-growth of epiblast or hypoblast into glands ever supported and nourished by mesoblast. Know that all this goes on with unerring precision, but with almost endless variation in proportion, with countless differences in form and function of cell, with an ordered cycle of chemical changes so wide in its range, so varied in its detail, that we seem to be only at the threshold of a knowledge of it. Remember that this development proceeds with measured step to a certain definite extent only, that then in spite of all kinds of variation in supply and demand, and of adverse and favourable conditions, a certain level of cell life and growth is maintained for a more or less determined period, and that then first here, then there, the processes seem to abate and fail, the flame of life seems to flicker until the unknown and wonderful changes of age draw on. I have failed to bring up before you a tithe of the marvels of the full development of a man from a single fertilised cell, or of the equally marvellous maintenance of his full manhood through the years of maturity and of the gradual decline into old age. But even in my faulty picture of it we see the outworking of a wondrous law, obedience to which brings perfection of development, of life, and of health.

Now summarise our facts about cancer. Consider the disproportionate multiplication of certain cells, their imperfect, irregular, and useless differentiation; their failure to form Altmann's granules, their excessive affinity for and need for potassium, their insistent intrusion into surrounding tissues, their imperfect coöperation with the other cells, and, finally, their selfish greed which enables them to live when other cells are failing and perishing for lack of nourishment—what is it all but a failure of, or a revolt against, that great cytological law or impulse which first manifests itself in the primary division of the ovum, and lasts on till the death of the organism? Cancer is not a disease attacking the body from without, it is the result of a breach or failure of fundamental cell law; a law of which we know only the results; a law so majestic that obedience to it results in perfect development, perfect health, the full measure of days, and disobedience to it may slowly spell out all the inscrutable woes of cancer.

Let us look now at certain conditions which are known to exert an influence on the causation of cancer, and see what confirmation they afford to this view of the nature of cancer.

1. *Age.*—And first it is fully established that cancer is greatly influenced by age. In man its incidence rises with

FIG. 3.



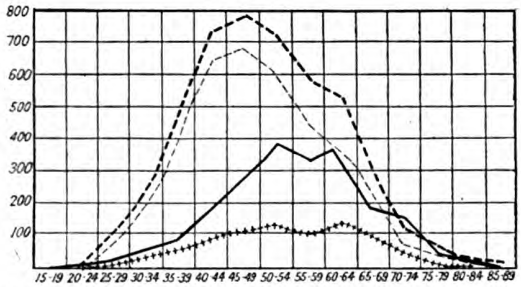
Mortality from cancer per million living at each of five groups of ages from 35 years upwards (1906).

each decade after the third. Of animals this is as true as of man. Thus the average life of mice in laboratories is three years, and sporadic cancer occurs almost invariably only after they have reached the age of two. It is from India, where the cow is a sacred animal, and is allowed to live to old age, that we have most evidence of the occurrence of

cancer in that animal. What we have so long known in the case of man, therefore, must not be regarded as in any sense an "accident" or peculiarity in him—it is one of the fundamental facts of cancer. (Fig. 3.) Cancer is undoubtedly a disease that generally arises in cells that are growing, or have grown, old. But senility of tissue is not a necessary condition of its growth, and indeed is not a favouring condition. Who of us has not been impressed by the terribly rapid advance of the disease as it occurs in young adults? Who has failed to notice the equally slow and difficult progress it makes in some old people? Of all conditions which influence the rate of progress of cancer in any particular site, I know of none more potent for mischief than the youth of the individual. From the cancer laboratories we get most definite statements that it is in young mice that cancer grafts grow with most certainty and with most rapidity. So important is this that Bashford has had to point out that, before a just comparison can be made between the results of inoculations under varying circumstances, it is absolutely essential that the experiments should be carried out in animals of known age and of the same age. Now this fact—supported alike by clinical human experience and by experimental animal experience—teaches us that the condition precedent to cancer is not in the nutrition of the tissues outside the cancer cell but within the cancer cell itself. The external conditions for the growth of the cancer cell are more favourable in the young than in the old, and a cancer cell having once started on its errant course can profit to the full from the greater nutritive vigour of the young. Incidentally this fact is a strong indication that cancer is not an infective disease, allied to bacterial invasions. So far as is known of them, old age is not a favouring factor; and it is the veriest negation of all our knowledge of these diseases that a condition favourable to their origin is unfavourable to their spread.

2. *Sex.*—It is well known that cancer is more frequent in women than in men, and that its incidence increases earlier, and attains its maximum sooner in them than in men; after the age of 70 the incidence is practically the same in the two sexes. The greater frequency in women is due to the special liability to the disease of the generative organs of that sex. (Fig. 4.) I have prepared a chart founded on the

FIG. 4.



Unbroken line = cancer in males. Thick broken line = cancer in females. Thin broken line = cancer of uterus, vagina, vulva, and breast only. Crossed line = cancer in females, excluding cancer of uterus, vagina, vulva, and breast.

statistics of the Middlesex Hospital (see Third Report from the Cancer Research Laboratory). The chart shows the close parallelism of the cancer curve in women and in their generative organs only, and the near approach of the curve for women, when we exclude disease of their generative organs, to that for men. In other words, the different incidence of cancer in the two sexes is not a sex difference affecting all the body tissues, but is the result of the special liability to the disease of organs possessed by one sex only. Now these organs—chiefly the breast and the uterus—have a definite functional life which does not correspond at all with the life of the individual, but starting at about 14 usually begins to terminate about 50, and during those years these organs are the seat of frequently repeated periods of great cellular activity followed by periods of decline and atrophy. It is, I believe, because of this fact, that these organs are specially prone to cancer as they get old—before the rest of the woman ages—and so we see the explanation of the facts that cancer is more frequent in women than men, and that its age-incidence differs in the two sexes.

3. CHRONIC IRRITATION.

Of the reality and importance of chronic irritation as a condition precedent of cancer I cannot stay to speak, nor need I: the facts are too well known. Attempts have been made to find the underlying cause of cancer when it follows chronic irritation in some change in the subepithelial tissues, and the Hunterian lectures of my colleague, Dr. Victor Bonney, on this subject are no doubt fresh in your memory. He showed that interference with the continuity and perfection of the subepithelial elastic tissue layer always preceded a carcinomatous growth, and, conversely, that cancer never originates in perfect normal tissue. It has been objected that his beautiful preparations fell short of a demonstration, that the changes shown were antecedent to the earliest development of cancer, and that they were as compatible with consequence as with precedence. It is, however, surely a striking fact that these changes are only met with at the seat of the primary growth and in the nearest lymphatic glands, and not in the true secondary growths. But while accepting Dr. Bonney's demonstration, I think we cannot for a moment regard any change in the subepithelial tissue of a part as the sole or most significant change in what have been well called "precancerous conditions." The essential features of such chronically irritated and precancerous tissues are increased cell formation associated with defective differentiation or cell development, and the changes in the subepithelial tissues may be either a result of this or another expression of similar nutritive changes.

The cytological effects of what we call chronic irritation are essentially two—increased cell multiplication and defective intracellular metabolism. Now the life of a cell is not to be expressed in periods of time, but in terms of its multiplication or proliferation. An epithelium does not become old because its individual cells have existed for a particular length of time, but when the multiplication of the cells necessary for its maintenance has been repeated a certain great number of times. Therefore chronic irritation, by adding to the frequency of cell division, is producing the special condition of cellular old age; it is, indeed, equivalent to the ageing of a tissue. Its other effect is equally significant. The imperfect cell development and metabolism carried on for generation after generation of cells is clearly akin to senile defects in cell growth and metabolism, as shown, for instance, in diminished secretion and in the impairment of all nervous functions. The word "irritation" is rather apt to suggest a stimulating process; it is important to remember that chronic irritation is the most effective mode of hastening on changes closely akin to, though not identical with, those of old age—the conditions in which we have seen cancer to occur most often.

4. *X Rays.*—Prolonged exposure to X rays may undoubtedly cause cancer. The evidence of the influence of X rays upon cell life is most important. Lazarus-Barlow and Somerville Hastings have shown that in the ova of Ascarides exposed to X rays the division of the cells is more rapid than in "controls," while fewer of the ova come to maturity. If we look at the hands of an X ray worker we see the same thing—increased production of epidermic cells, with imperfect development of the too numerous cells. Think of this progress carried on and on, will it not cause a premature ageing of the formative epithelial cells, associated with an imperfect elaboration of the cells?

5. *Alcohol.*—The last etiological factor to which I can refer is alcohol. To some extent this causes cancer by directly or indirectly inducing chronic irritation; but let us note that it is a protoplasmic poison—that is, a substance which directly interferes with, and mars, cell metabolism and cell life. The influence of alcohol on the incidence of cancer is really important. Dr. Tatham's statistics of the mortality of various occupations from certain diseases revealed the fact that cancer is twice as frequent among brewers and London publicans as among clergymen, and that the cancer incidence in any trade varies with the attendant habits as regards alcohol. Dr. Newsholme has dealt with this subject in the light of figures obtained from the United Kingdom Temperance and General Provident Institution, and has shown that the mortality from cancer

among the insured in that institution, if represented by the figure 100 among the non-abstaining males, would be represented by 72 among the abstainers. He laid emphasis upon the fact that this statement was based upon scanty evidence; I have therefore endeavoured to increase the evidence, and Sir Thomas Whittaker has very kindly brought the figures up to date; and the following table, which is prepared in identically the same manner as that given by Dr. Newsholme, shows that from the larger number of lives the same conclusion is to be drawn:—

United Kingdom Temperance and General Provident Institution.

Ages of insured persons and of persons dying in each group.	Aggregate population or years of life at risk during years 1891, 1896, 1901, and 1906.		Deaths during the years 1891, 1896, 1901, 1906. From all causes.		From malignant diseases.		From malignant diseases (males alone).		Ages.
	Abstainers' section.	Non abstainers' section.	Abstainers' section.	Non-abstainers' section.	Abstainers' section.	Non-abstainers' section.	Abstainers' section.	Non-abstainers' section.

PRIMARY CANCER NOT ALWAYS SINGLE.

It comes to this, then, that all these so-called causes of cancer—age, chronic irritation, X rays, and alcohol—agree in being conditions that wear out the cells of a part; they add to the number of cell generations, they deteriorate the evolution of the individual cell, they appear to lessen the hold over the cell of the great primal cell law, and so they cause cancer. One objection that may well be raised to this view lies in the occurrence of primary cancer as a single lesion. It is easy at the first blush to find in this a complete refutation of what I have been trying to establish. But the more I have thought of this objection the less convinced I am of its worth. A physiological essay *de senectute* would be very valuable. Wherein lies the true essence of senility? Is it simultaneous in all our tissues? Are we animated illustrations of Oliver Wendell Holmes's "wonderful one-hoss shay"? And, if not, if one organ or tissue may grow old before its fellows, are we quite wise in holding that all the individual cells of a given organ must grow old together?

But we must not lose sight of the fact that cancer is not always single in its primary seat. My colleague, Dr. Young, among others, has published a number of instances of multiple primary cancer in the Fourth Report of the Middlesex Hospital Cancer Research Laboratory. In my limited experience I have seen such cases as these: in one case a woman presented three cancerous growths in her left breast, all of them noticed at the same time, no one of them larger or notably different in any way from its fellows. I removed the breast, and have one half of it on the table before me. Three times I have been consulted by women with a tumour in each breast, small, far distant from each other, and, except for enlarged glands in the axilla, without evidence anywhere of metastasis, so that I could only regard them as simultaneous primary cancers. One of these patients submitted to amputation of both mammæ in 1899, and has remained without evidence of metastasis until now, so that it is reasonably certain that in her case one breast was not infected from the other. Many times I have seen cancer occur in the breast at an interval after removal of the opposite breast when there was no evidence of metastasis elsewhere, and the subsequent progress of the case was so exactly similar to the disease occurring in one breast only, that I was forced to see in it a new attack of the disease, and not the development of a metastasis from the earlier tumour. Twice over it has happened to me to be called to do colotomy for chronic intestinal obstruction that had become complete, and in which examination of the rectum revealed a stenosing growth within easy reach of the finger, but further examination showed a second independent, annular carcinomatous growth, in one case in the descending colon, and in the other in the transverse colon.

Last year I was consulted by a patient whose left breast had been removed for cancer in 1902; she had had three subsequent operations. She came to me complaining of an extremely severe pain along the distribution of the ulnar nerve, and I found a very dense, and firmly fixed lump of growth close to the coracoid process. I advised her to try what radium would do to relieve her pain; immediately after exposure to radium for 48 hours, carried out by Dr. Finzi, she lost all pain in the arm and hand, and it never returned. The radium was applied on a few subsequent occasions in the hope that it would lead to the disappearance of the growth—of this happy result I saw no proof; but meanwhile an epithelioma developed in the left labium majus, ran a rapid course, and was the cause of her death in December, 1909.

In the lip I have, on several occasions, seen two or more quite independent primary growths, and in June last I saw a very early epithelioma of the tongue which proved, when subsequently removed by Mr. Spencer, and examined by Dr. Bashford, to be starting from four separate centres. Of multiple rodent ulcers I have had very numerous instances. Multiple epithelioma in lupus and in X ray dermatitis is also well known, and from Kashmir we are told of multiple kangri cancer. Were I, on the other hand, to try to give you any adequate conception of the irregular incidence of old age, I should need a separate lecture and a much wider knowledge than I can even pretend to possess. But let us take one example—and that the best known of all, the hair—what numerous varieties in the senile changes in the hair we see! It may fail to grow without change of colour; it may lose its colour and persist in growth; again, these variations may affect the hair in one part of the body only, or in small areas only, or even be limited to the product of a single hair follicle. If age can thus influence the growth of certain hair-forming epithelium, why may not the age-effect that leads to cancer start in a single epithelial cell?

IMMUNITY.

The only other aspect of the cancer problem to which I would refer is expressed in the word *immunity*. This word is specially associated with the processes by which we are enabled to withstand successfully the attacks of pathogenic organisms. It is clear, however, that if cancer is not due to any similar cause, but arises from a failure to continue the cellular development of a part exactly in accordance with the pattern of normal growth, we must not look for immunity from this disease along the lines in which we find it for infections. Careful search by many observers has failed to find evidence in cases of cancer of the activity of these protective forces which play so great a part in the life-history of infective diseases. In the last Croonian lecture at the Royal College of Physicians Dr. Andrewes gave a very full account of the part played by leucocytes in protecting against infection. There is no like tale to be told of their activity and power against cancer. Blood changes there are in the *late stages* of the disease, when other factors than the presence of a malignant growth are active, but none of a protecting character have been demonstrated in the early stages of cancer, when that disease alone is present to disturb the harmony of nutrition. We have in this another fact which strengthens the contention that cancer is not an infection disease. If the disease differs wholly in nature from those infections in which immunity has been chiefly studied, the problem of cancer immunity will also be different.

Accepting the view of cancer that I have tried to submit to you, cancer immunity might be evidenced in one or more of the following ways:—

1. The power of living cells to conform to the law of normal development and to avoid that increased multiplication,

defective differentiation, and tendency to intrude themselves into, and grow in, neighbouring cell territories, which together connote cancer.

2. Opposition to the intrusion of cancer cells into, and their development in, heterologous tissue.

3. Inhibition of the growth of cancer or destruction of living cancer cells.

What can we say under each of these heads? Does clinical experience or experimental pathology throw any ray of hope across the dark sea of malignant disease? They do. The deep impress of the primal laws of development holds the cells of our tissues in true and loyal obedience to the very end, in the almost infinite majority of cases, and in the large majority of individuals. The incidence of disease, and immunity from its initial attack, are of course complementary, and the same fact can be expressed either in terms of disease or in terms of immunity. Thus the public have been distressed by the oft-repeated statement that 1 out of every 8 women who reach the age of 35 dies subsequently from cancer; and of the men who attain 35 years, 1 of 13 dies from cancer! This no doubt is true, but we can express the same fact in terms of immunity, and say that 7 out of the 8 women and 12 out of 13 men of 35 years of age will not die from cancer! This is the great initial fact of cancer immunity—that in spite of added years, and of all the unfavourable conditions which tend to wear down the obedience of cell life to its fundamental laws, 90 per cent. of men and women who pass down the hill of life hold this dread enemy at bay. The two ways of quoting our cancer statistics always remind me of a scene in that incomparable allegory which we all had read to us in our childhood, and therefore too often put aside in our maturity. You remember, sir, that when the Pilgrim is taken into the Interpreter's house to have some of the mysteries of human experience explained to her she is shown, to use Bunyan's inimitable words, "a room where was a man that could look no way but downwards, with a muck-rake in his hand. There stood also one over his head with a celestial crown in his hand, and proffered him that crown for his muck-rake; but the man did neither look up nor regard, but raked to himself the stones, the small sticks, and the dust of the floor." The 1 in 10 of failure that our pathologists tell us of is "muck-rake lore"; the 9 in 10 of success in the great drama of cell-life is like the angel's crown—it is immunity.

Of the second kind of immunity—the opposition to the intrusion of cancer cells into the heterologous tissue—we have plenty of evidence. There is first of all the difficulty in cancer grafting, and then the fate of many of the cancer cells and minute cancer emboli that get into lymphatics and blood capillaries; the majority of them are overwhelmed by the opposing influence of the endothelial cells, and only one here and there is ever able to survive. Or let us recall our clinical experience of the very slow progress of many cancers, of their long-enduring limitation to their primary site, in some cases, and of the extraordinarily long period—amounting to ten or even more years—that may elapse between the removal of an active cancer and the development of a metastasis. Do not all these well-established facts tell us that the organism is not left powerless, defenceless, before the intruding cancer cells, and that the opposing foes are not so unevenly matched as students of the failures of these saving powers—the "muck-rake" students—would persuade us? There is a force of immunity which can protect, and does protect, against the chief mischievous power of malignancy; and when a surgeon asserts that every case of cancer can be cured by a sufficient and sufficiently early operation, I can assent when I remember the reality and the efficiency of this force of immunity, which is his great ally.

The third form of immunity is what is popularly known as the "cure of cancer"—*the disappearance of cancerous growth*. Those who are studying the disease in mice report to us that in these animals it is quite a frequent occurrence for a grafted cancerous growth, after attaining some size, to slowly shrink and disappear, and in some series of experiments a large proportion of the grafts that have "taken" have, after a period of growth, spontaneously vanished. Among the 500 sporadic cases of mouse cancer observed by Bashford this event has been witnessed only two or three times. In human pathology, I fear, it is a still less frequent fact, *but it undoubtedly is observed* It is most frequently seen in the gradual absorption and disappearance of small secondary nodules in the skin and subcutaneous tissue. It is occasionally witnessed on a grander scale. Many years ago I showed a patient at meetings of the Clinical Society of London who recovered spontaneously and completely when she seemed to be at death's door from cancerous deposits in the lung and the neck of the femur, secondary to cancer of the breast. She remained well for several years; unfortunately, I have been unable to trace her for the last four years. More recently I have had an equally satisfactory and striking case.

A woman, aged 52 years, was admitted to my cancer ward of the Middlesex Hospital on Feb. 28th, 1906, suffering from advanced cancer of the uterus; that organ was fixed in the pelvis, the cervix was ulcerated, and masses of growth were felt invading the anterior wall of the rectum; she suffered from constant discharge and irregular hæmorrhages. In February, 1907, I find this note: "The vaginal cervix is the seat of a nodular growth, which is hard, but apparently not ulcerated; it extends all round the cervix and infiltrates the posterior wall of the vagina and anterior wall of the rectum. There is also some extension down the left vaginal fornix. The uterus is fixed." She became slowly but steadily worse, and for many months was unable to leave her bed, owing to frequent hæmorrhages and the consequent weakness and the pain, which movement increased. In the early summer of 1908 she gradually lost the use of her lower limbs, and the paralysis extended to both upper limbs until she was literally unable to move hand or foot. My colleague, Dr. Campbell Thomson, kindly examined her on several occasions and satisfied himself that the paralysis was due to exaggerated peripheral neuritis. During the late summer she improved, and when I returned from my holiday at the end of September, 1908, I found that she could just move her hands a little; she was also stronger, with less pain and less discharge, and a local examination showed that the uterus was less firmly fixed than before. Not to weary you with details, the patient got quite well, all the local evidences of disease vanished, and I made this note in July, 1909: "Uterus is small, senile; vagina narrowed at its upper end, vaginal cervix very small, no ulceration or growth to be felt in cervix or vagina; uterus is mobile. The original disease has entirely disappeared."

After keeping her for several months to make sure of her recovery we had to discharge her from our Cancer Charity as she no longer fulfilled the necessary condition of suffering from cancer, and she now earns her living by needlework.

Here is another case:—

(*a*)[1] A trained nurse discovered a lump in her left breast in 1896 when she was 46 years of age. In June, 1897, Dr. Anderson of Faversham removed the breast, and in September, 1898, he removed a lump from the axilla. In January, 1899, she came under the care of Mr. Farnell of Eastbourne, who removed a recurrence in the axilla and two or three nodules in the skin. In May of the same year he thoroughly cleared out the axilla, as there was evidence of more extensive disease there. In November, 1899, and in March, 1900, he excised small recurrences in the axilla. In May, 1900, he again operated upon the axilla and found it impossible to remove the growth under the arm. I saw this patient in September, 1900; the wound in the axilla was unhealed, and there was a firmly fixed mass of growth just below the clavicle; the upper limb was greatly enlarged from œdema. Mr. Farnell and I advised the patient to submit to a certain treatment, which was forthwith carried out. The wound quickly healed; the œdema of the arm and all evidence of the presence of a growth disappeared.

I saw this patient last month, after an interval of ten years, and found her enjoying excellent health; the scars of her numerous operations are the only sign that she has ever been the subject of cancer.

Here is another case:—

(*a*) A single woman, aged 41 years, was admitted under my care in January, 1900, with cancer in both breasts. The disease had been noticed on the right side for two and a half years, and there had been ulceration for a year and ten months; on the left side it had been known to exist for six weeks, and the lump had doubled in size in that time. The disease infiltrated the entire right mamma and the skin covering it, and fixed the part to the ribs beneath; there were enlarged glands in the right axilla and beneath the lower end of the right sterno-mastoid muscle. Several nodules of secondary growth were scattered around the primary growth, and above the nipple was an ulcerative surface measuring 2¼ inches by 3½ inches. There were also two areas of marked venous congestion of the skin, one below this breast and one over the pectoral muscle towards the point of the shoulder. In the outer part of the left mamma was a firm infiltrating mass the size of a large walnut, and in the left axilla were enlarged and tender glands. On Jan. 31st an operation within the abdominal cavity was carried out. Within three weeks the congested areas I have mentioned had become pale, the ulcer was healing, and the secondary nodules were smaller. By March 9th there was no nodule to be felt in the left breast, and I could only detect in that axilla one tiny gland the size of a buckshot; on the right side the lower half of the breast was free from all evidence of growth and the ulcer was healed. By March 27th all that was left of the originally extensive disease were two or three very small nodules of the skin of the chest. On April 18th symptoms of intestinal obstruction developed, an operation was performed, and I regret to say that this patient died quite suddenly while some adhesions were being separated. At the necropsy a few small nodules of growth were found in the subcutaneous tissue over the right breast. No other traces of cancer could be detected. A nodule removed in March presented characteristic appearances of spheroidal carcinoma with a relatively large amount of connective tissue.

[1] Cases marked (*a*) were treated by double oöphorectomy.

Here is another good case:—

(*b*)[2] A woman, aged 57 years, was first seen by me in July, 1903. Her left breast had been removed for carcinoma in April, 1900; four operations for recurrence had been performed since. There was a very considerable local recurrence, enlargement of the third costal cartilage, deposit in the lower flap and under the arm. All the growths have disappeared, the patient is in good general health, and continues at her work. I have seen her from time to time during the last seven years, the last time in October of this year; she was then quite well, except for a little superficial ulceration, which seemed to be due to the treatment that had been employed.

Here is a somewhat similar case:—

(*b*) A woman, aged 44 years, was first seen by me at Middlesex Hospital in September, 1909. Her right breast had been removed for carcinoma. There was an extensive secondary deposit in the chest wall with a wide and deep ulcer. Under treatment this ulceration rapidly cleaned and healed, and the growth has disappeared, leaving a very little thickening to be felt where before there was a mass of deposit.

Her health is quite good and she does all her work.

(*b*) A woman, aged 43 years, was first seen by me in May, 1909. Her left breast had been removed for carcinoma. There was a considerable secondary mass of growth in the lower flap and under the axilla. Under treatment the deposit has steadily decreased in size, and in November of this year there was only a slight thickening to be felt.

Her health is good and she is doing full work.

(*b*) A man, aged 44 years, was sent to me from another hospital as an incurable case in December, 1903. A columnar carcinoma of the rectum had been removed by Kraske's method. There was local recurrence of the disease, and a mass of growth the size of an orange protruded from the sacrum. Thirteen months later—January, 1905—the following note was made: "Good general health, doing all his work (as a postman), no sign of disease." In August this year, 1910, he was seen again, and gives this history. At the end of 1905 there was noticed a warty condition of the old scar; this ulcerated. It was removed, and proved to be a squamous epithelioma. The wound healed well, and he has had no further trouble.

He continues his work as a postman, and enjoys good health. He was seen in October of this year, nearly seven years after his first visit.

Several years ago I excised the left superior maxilla of a woman for cancer. Some months later her attendant in the country sent her back to me at the hospital with extensive recurrence; the cavity left by the removal of the bone was filled with a mass of growth. A year later the doctor asked me to see his patient again, and to my delight I found her in excellent health, and without a trace of the local disease.

(*b*) Another case that I can never forget was that of a woman who had had her left breast removed for cancer and subsequently came to the Middlesex Hospital Cancer Charity with local recurrence, growth in the glands of the neck, and a large brawny arm. She got quite well, and was able to earn her living again at the wash-tub. I had another similar case where the "brawny arm" got quite well, and all the recurrence of the disease disappeared.

THE HOPE OF CURE.

This is not an exhaustive list of such cases that I have myself seen, and I am sure that my experience is not singular. In some of them the disease was not "cured" in the sense of being wholly and permanently removed, but in several there is strong reason for thinking that this word "cure" may be justly used. In many of the cases treatment directed to this end has been carried out; in some there has been no special treatment. In my brief records of these cases to-day I have not mentioned the treatments employed, because my present purpose is not to vaunt a remedy but to state a fact—that cancer, even when advanced in degree and of long duration, may get better, and does sometimes get well. *There is cure of cancer*, apart from operative removal.

All therapeutic cures are obtainable only by the working of physiological forces, and the first hope of therapeutic success comes with the observation of the efficiency of unaided Nature to accomplish cure. You may say to me there is little comfort in all this; you enunciate a philosophical concept, and you tantalise by a record of very rare exceptions in the grey, grim drama of cancer. Not so. These cases, rare though they be, are the sun of our hope. In the darkness of night it is everything to know that there is a sun towards which the earth is revolving, and that if we fix our eyes on the East we shall soon see the grey promise of the dawn and then the many-coloured heralds of the golden sun itself. And as the victims of cancer call to us in the dark night of despair, "Watchmen, what of the night," oh! it is much to know that for cancer-stricken man there is also a sun of healing. We envy the astronomers who know so well the laws regulating the movements of the spheres, that they foretell the happenings of the universe with a precision that is the despair of workers in all the other branches of natural science. But with all their knowledge of these laws they cannot hasten on the day, or affect in one small circumstance the movement of a planet, or alter the destiny of a single grain of meteoric dust. But when the biologist shall know the laws that govern cell-growth, with a knowledge akin in its sweep and accuracy to that of the astronomer, he will have power—the power to prevent, to control, to cure, cancer.

[2] Cases marked (*b*) were treated by Roentgen rays by my colleague Mr. Cecil Lyster.

CONGRESS IN BERLIN.—A National Congress for the Study and Prevention of Infantile Mortality under the auspices of the *Gouttes de Lait*, will be held in Berlin from Sept. 11th to 15th, 1911. The committee of organisation will have charge of the Infants Department of the International Hygiene Exhibition to be held in Dresden from May to October, 1911. The general secretary is Dr. Kellner, professor and director of the Kaiserin Augusta Victoria Hospital at Charlottenburg.

FOREIGN UNIVERSITY INTELLIGENCE.—*Düsseldorf* (*Academy of Practical Medicine*): Dr. Bruno Oertel, *docent* of otology and laryngology, has been granted the title of Professor.—*Giessen:* Dr. Otto Kuffler has been recognised as *privat-docent* of Ophthalmology.—*Göttingen:* Dr. Fromme, assistant in the Surgical Clinic, has been recognised as *privat-docent* of Surgery.—*Gratz:* Dr. Alois Materna has been recognised as *privat-docent* of Pathological Anatomy.—*Halle:* Dr. A. Eberth, professor of pathology, proposes to retire at the close of the current session.—*Heidelberg:* Dr. Ernst Kürz has been appointed Director of the Institute of Forensic Medicine in succession to Dr. Knauff.—*Königsberg:* Dr. Arthur Brückner, *privat-docent* of ophthalmology and surgeon to the ophthalmic clinic, has been granted the title of Professor.—*Leipsic:* Dr. Heineke has been appointed Extraordinary Professor and Director of the University Surgical Clinic in succession to Dr. Perthes, who goes to Tübingen.—*Lyons:* Dr. Courmont, *agrégé*, has been appointed to the chair of General Pathology and Therapeutics.—*Naples:* An Academy of Marine Medicine is to be established with departments for Naval Surgery, Tropical Diseases, and Climatology.—*Tübingen* (*Medical Missionary Institute*): Dr. Fiebig, the recently appointed director, has been obliged by illness to resign the post.—*Valencia:* Dr. Juan Campos Fillol has been appointed Adjunct Professor of General Pathology.—*Vienna:* Dr. Karl Fleischmann has been appointed Director of the Rothschild Hospital.—*Warsaw;* Dr. S. M. Maximovich has been appointed to the chair of General Pathology.

MEDICAL JOURNALISTS' CONGRESS.—The first Congress of French Medical Journalists, which has been organised by the Association of French Medical Journalists, will take place in Paris on March 23rd, 1911. The President is Dr. Maurice de Fleury and the secretary-general is Dr. Cabanès, whose address is 9, rue de Poissy, Paris (5e). The subscription is 6 francs, except to foreign members, who do not pay any subscription. This amount is payable before Feb. 1st, 1911, to M. Le Sourd, 49, rue Saint André des Arts, Paris (6e). The Congress will be held in the hall of the Hôtel des Sociétés Savantes, rue Danton, Paris, and will begin at 9 A.M. on the date fixed. The questions on the agenda are as follows: (1) On the Right of Reproduction of Medical Articles, opened by M. Vitoux; (2) Relations of the Medical Press with Congresses and other Movements of Interest for the Art and Practice of Medicine, opened by M. Ausset; (3) Organisation of an Immediate Reserve or Benevolent Fund, opened by M. Duchenne (Chatel-Guyon); and (4) Usurpation of the Title of Doctor, opened by M. Dieupart. The titles of communications intended to be presented to the Congress must be sent to the Secretary-General before Feb. 1st, 1911. A dinner by subscription will also take place the same evening at 7.45 P.M. Special reductions in railway rates may be obtained by members of the Congress travelling over the French railway companies' systems, by filling up and returning a form which will be supplied by the secretary of the Congress upon application.

The Bradshaw Lecture

ON

THE RESULTS OF BRONCHIAL OBSTRUCTION.

Delivered before the Royal College of Physicians of London on Nov. 1st, 1910,

BY G. NEWTON PITT, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO GUY'S HOSPITAL AND LECTURER ON MEDICINE.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to thank your predecessor in the chair for the honour he has done me in nominating me for this lectureship to-day, and to express the diffidence I feel in choosing a subject on which it may seem there is not much that is new to be said.

We are met to-day to do honour to the memory of Dr. William Wood Bradshaw, who, it would appear, was a man of wide interests; he contributed papers on such subjects as the use of cod-liver oil in chronic rheumatism, on narcotics, on abdominal abscess, and other non-professional articles to the *Miscellany* and elsewhere. Born at Bristol in 1801, according both to Foster's "Alumni Oxiensis" and to the inscription on his grave, he was educated at the Westminster and Middlesex Hospitals, taking his M.R.C.S. in 1833. In the early part of the same year he became M.D. Erlangen. He became an Extra Licentiate of this College in 1841, after examination by the President and the "Elects," which entitled him to practise beyond seven miles from London. In 1854 he was elected a Fellow of the Royal College of Surgeons of England. In 1859 Dr. Coplans Hawkins and Dr. R. P. Smith nominated him as a Member of this College, which nomination was approved. At the mature age of 43 he matriculated at Newton Hall, Oxford, and was granted a degree in 1847 without any examination. He married the widow of a wealthy jeweller at Andover, and, according to Mr. Rickman Godlee, to whom I am indebted for his portrait and for much of this information, her money was to be left away in case she re-married; but they bought the reversion, married, and settled down at Reading. He seems to have been a cultivated, refined, somewhat eccentric man with a rather theatrical manner, and never did much practice. He died in 1866; his widow founded a lectureship at each of the Colleges in order to perpetuate his memory.

THE RESULTS OF COMPRESSION OF A BRONCHUS.

The results of compression of a bronchus may be the following.

1. The lung may be slightly reduced in size. There may be definite diminution in the entry of air, but the resonance may be unaltered, and even post mortem beyond an increase in the amount of mucoid contents, and a diminution in the amount of air in the lung, this may be all that can be observed even when there has been definite pressure on the tube.

2. The chest may be hyper-resonant, the lung over-distended, and the diaphragm displaced down abnormally. This occurs only with partial obstruction of the tube when respiration is vigorous, and will be discussed under the results produced by aneurysm.

3. The lung may be reduced in size, airless and solid from collapse. The chest will be dull on percussion. This results when the obstruction to the tube is complete or when respiration is feeble. It may occur within a few hours, and was studied by Lichtheim by observing the effects of introducing foreign bodies into the bronchi so as to completely block them, but practically complete obstruction is generally due to other causes and rarely to the presence of a foreign body. In the early stage the bronchi beyond the obstruction are empty. The lungs in the first and second conditions also tend gradually to become more or less airless.

4. The bronchi become filled with retained secretions, at first chiefly mucus, but catarrhal changes soon ensue, cells accumulate, together with purulent and inflammatory products.

5. Secondary inflammatory changes take place, due partly to the entry of secretions into the alveoli, so that what has been called a retention pneumonia ensues; the alveoli fill with catarrhal cells and giant cells appear, although they are unconnected with tubercle, as has been shown by inoculating animals with the products. When alveolar walls remain long in contact, organisation with obliteration takes place and new connective tissue is formed. The bronchi normally often contain a few staphylococci and streptococci, which when retained in suitable media begin to develop, with the result that pyrexia and a more or less acute pneumonic change develops.

The changes that have taken place so far may all pass away and leave but little damage; but two further changes soon take place—a general fibrosis of the lung beyond the obstruction and a bronchiectasis. These ultimately develop, whatever be the initial process, if the obstruction persist.

6. Dilatation of the tubes. This does not take place equally in all the tubes obstructed, and its distribution is largely determined by local causes. When only one branch of a bronchus has been pressed upon, the dilatation is limited to the tubes in its area. Generally the tubes at the posterior and lower part of the lung are the most affected, probably because the secretion tends to stagnate there and set up local destructive changes as the patient is in the semi-recumbent position.

Normally there is a constant secretion of mucus in the bronchi, which passes imperceptibly out into the larger tubes and thence to the trachea, but we are quite ignorant what is the amount normally secreted in 24 hours. When a bronchus is occluded the mucus at once begins to accumulate and is capable of being secreted under pressure, so that as with an obstructed gall-bladder the tubes become over-distended. Now bronchial contents cannot pass through the bronchial wall on account of the basement membrane; they can only pass out by the bronchus, or be sucked back by inspiration into the alveoli which remain patent, and so on into the lymphatics and the glands. Normally the contents pass almost entirely by the bronchus, because the initial act of expiration consists in the contraction of the lung by its own elasticity, which as the alveoli empty drives the secretion out of the smaller bronchioles into the larger tubes, to be then carried on by the forcible muscular expiration. With a collapsed lung this initial mechanism fails. As the alveoli become blocked, there is a greater suction on those that remain, and this leads to further occlusion of the alveoli, but the movement of the chest on the affected side is always more or less feeble. The result is that, whether the lung is distended or collapsed, the bronchi become distended with mucoid or muco-purulent contents under high pressure, and hence the walls yield. Owing to the interference with the circulation, which is largely dependent on the suction of the alveoli as they open up with inspiration, the arteries being on the proximal and the veins on the distal side, the tissues are insufficiently nourished, and this, added to the local irritation, causes the bronchial walls to deteriorate, so that the elastic and muscle fibres tend to disappear and local dilatations occur.

It is an old controversy as to whether inspiratory or expiratory efforts are the more efficient in the production of bronchiectases, and I am sorry to say that at the present day the latter theory seems to have the more advocates. In the cases under consideration it is difficult to see how violent expiration, compressing the lung forcibly, as with a cough, can throw any greater strain on the inside of the bronchi than it does on the outside. If the same pressure is applied all round the wall of a bronchus it cannot tend to dilate it. The increased pressure of the contained air is the result of the pressure applied to the outer surface of the bronchus. On the other hand, if it is borne in mind that aspiration is applied to the surface of the lung by inspiration, which tends to open it up, and if the alveoli fail to respond, strain is thrown on the deeper parts such as the bronchi; if there is no obstruction they open up and fill with air from the trachea, but when the bronchus is obstructed they must be subjected to strain which tends to dilate them. The feebleness of the respiratory movements spares them greatly, but the contracted condition of the lung tends to set up an inspiratory dyspnœa, and paroxysms occur from time to time, especially with exertion, which must aspirate the tubes and gradually make them dilate.

Consequently we do not find marked dilatation except when there is also in these cases definite fibrosis. The slighter degrees of dilatation are associated with but slight consolidation of the lung. The presence of pleuritic effusion

usually inhibits, or entirely prevents, the dilatation of the bronchi, because the lung not being in contact with the pleura is no longer held up by capillary attraction between the two surfaces, and therefore is not subjected to so much aspiration. There is no evidence that connective tissue in contracting is capable of producing traction on the tubes at all comparable with that exercised by the powerful suction action of inspiration. It was noted many years ago by Dr. Charlton Bastian that in one-fifth of all cases of cirrhosis of the lung the tubes are not at all dilated. This is what might naturally be expected, as respiration would probably be feeble in many, but if the fibroid change were the essential cause of bronchiectasis it would be inexplicable.

It has been suggested that the accumulated weight of the contained secretions will suffice to distend the terminal tubes when a bronchus is compressed by an aneurysm. The terminal tubules are not the ones that are especially dilated, and the tubules lie in a closed box, the chest, and are supported outside by the same pressure as that inside them. The pressure inside the chest may be slightly increased, but there is no difference between the pressures inside and outside the bronchi, which is the important factor.

The essential factors which lead to dilatation of the tubes would therefore appear to be local changes in the walls, the accumulation of secretion under tension, and the effects of inspiration on a lung which is not capable of expanding satisfactorily.

7. Fibroid thickening of the lung. There are several factors which conduce to this result: inflammatory and organising connective tissue changes result (*a*) from the retention of the secretions, (*b*) from the prolonged collapse of the alveoli, (*c*) from the broncho-pneumonia, (*d*) from the peri-bronchial changes which follow on the destruction of the bronchial epithelium, which generally takes place, and finally (*e*) from the interference with the pulmonary and lymphatic circulations which normally depend on the opening up and the contraction of the alveoli. Moreover, when we bear in mind that in health the alveolar surface of each lung amounts to 100 square metres, each air cell being bathed in a film of blood 10μ in thickness, we can realise what a difference it must make to the nutrition of the tissues when the alveoli fail to open and the amount of the circulating blood is enormously reduced; hence retrograde fibroid changes must gradually develop. The fibroid change is therefore also a natural sequence of obstruction, but the causes are not quite the same as those which produce the bronchiectasis.

8. Secondary infections producing a septic pneumonia breaking down into abscesses are not infrequent and vary with the cause; in some they are essential and early, in others a late and accidental development.

9. Gangrene. This especially occurs with malignant disease and when the pulmonary artery is occluded. The communication between the bronchial and pulmonary arteries is a free one, but varies in different cases, and hence gangrene does not always occur even when the pulmonary artery is compressed. The condition may also result from a very virulent infection.

10. Putrefactive changes. Although the bronchi are often dilated, the contents are not always foul. The change is always a serious one, as it accelerates the destructive changes in the lung and introduces a severe toxic poison into the system; the organisms are usually anaerobic, and hence are but rarely cultivated.

11. As a secondary result of the bronchiectasis, especially if foul, there may be a pleurisy or an empyema.

Although stridor is a symptom that at once attracts attention, it is to be noted that it was present in but a very small proportion of the cases examined; it is marked when the trachea is involved, but otherwise was noticeable in only two or three of the cases of growth and aneurysm, yet severe dyspnœa was common.

CAUSES OF BRONCHIAL OBSTRUCTION.

Bronchial obstruction may arise from causes without or within the bronchus. Usually only one bronchus is affected, but in some cases the trachea is involved, as well as one or both bronchi. The external causes producing compression are:—

1. Aneurysm of the aorta (35).
2. Malignant disease (56).
   (*a*) Bronchial glands—
      (1) Primary, usually sarcoma (26);
      (2) Secondary to growth at a distance (6).
   (*b*) Œsophagus, epithelioma (16).
3. Enlarged caseous or suppurating glands (12).
4. Gummata (2).
5. Abscess (3).
6. Dilated left auricle (1).

The internal causes are:—

1. Bronchiolitis.
2. Syphilitic ulceration with scarring (5).
3. Primary malignant disease of a bronchus (usually columnar-celled carcinoma) (8).
4. Foreign bodies in the bronchus (8).

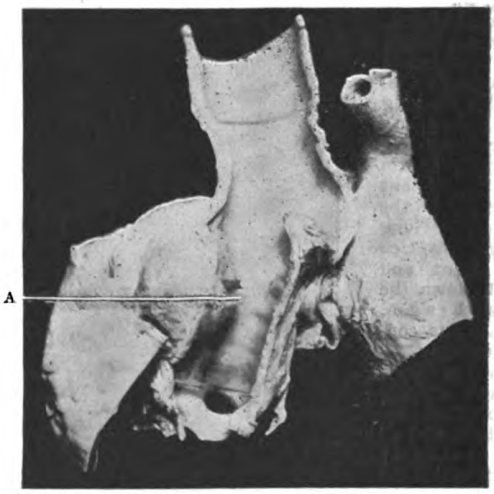
The material I propose to discuss is collected from our records at Guy's Hospital, and I desire to thank my colleagues for their kind permission to refer to cases under their care. I shall only discuss the general results and give a few illustrative cases.

ANEURYSM OF THE AORTA.

During the period taken, out of 11,000 post-mortem examinations there have been 140 aneurysms of the thoracic aorta. Thirty compressed the left bronchus, and 16 of these eroded into it; five compressed the right bronchus and none eroded it. To contrast the results of compression produced by the various causes it may be noted that in this series, 16 cases—i.e., one-half—there was bronchiectasis beyond the obstruction, but in only eight was it associated with a marked fibroid thickening of the connective tissue and increased pigmentation of the lung with a thickened pleura. In several (6) there was also an acute terminal pneumonia, and in four an acute septic pneumonia; in 3 there was an acute gangrene, and sometimes there was an acute pleurisy, but only once was there a pleuritic effusion. When there was no definite dilatation of the tubes the lungs generally showed bronchi full of muco-purulent secretion, often with collapse and a more or less airless lung.

The dilatation of the tubes takes place only in the part of the lung beyond the obstruction and is irregularly distributed, being generally least marked in the anterior part. The amount varies greatly; in some cases the distension of the tubes is but slight, when the lung may be also collapsed or pneumonic. Marked increase in the fibrous tissue, as it occurs less frequently, appears to be to some extent a secondary change and to be partly set up by the absorption of the irritating contents. In advanced cases the fibrous trabeculæ stand out, the lung is very tough, and may be riddled with inter-communicating cavities. In only one in 12 was an acute gangrenous condition noted, although in many the contents were very foul. The bronchiectasis requires at least two or three months in which to develop, but occasionally it took a year or more, and it is very remarkable how very latent the constitutional symptoms may be so long as the changes are limited to the fibroid lung beyond the obstruction. When much foul secretion is expectorated the healthy part of the lung is apt to become infected, and if an acute

FIG. 1.



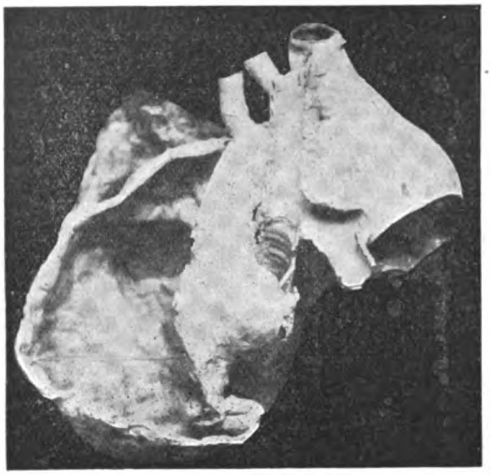
Trachea and bronchi opened from behind to show that an aneurysm of the transverse part of the aorta presses on the anterior and outer part of the left bronchus. In this case the aneurysm is just beyond the transverse arch and has ruptured into the bronchus at A.

septic pneumonia develop the disturbance to health is intense.

The *ascending arch* is not in very close relationship with the right bronchus, and only occasionally will an aneurysm of this part (usually a saccular one) compress the bronchus, and then on its anterior surface; not infrequently it will also involve the trachea; in none of the cases did it rupture into the bronchus. Occasionally the azygos vein, which is in close relation to the right bronchus, may also be compressed, and this may be the explanation of the only case with pleuritic effusion. In none of the right-sided cases did the breath sounds entirely disappear, nor did a local bronchiectasis develop.

A sac connected with the latter part of the *transverse arch* may compress more or less completely the left bronchus on its outer and anterior surface, and often the trachea as well, and very rarely the left pulmonary artery which lies above the bronchus (Fig. 1). This arterial stenosis probably accelerates retrograde changes in the lung and the development of the fibroid thickening, but it did not in any case lead to gangrene. In no case did an infarct form, and in only one did an aneurysm rupture into the pulmonary artery. When the aneurysm comes off lower down it will compress the bronchus from behind and on its outer side (Fig. 2).

FIG. 2.



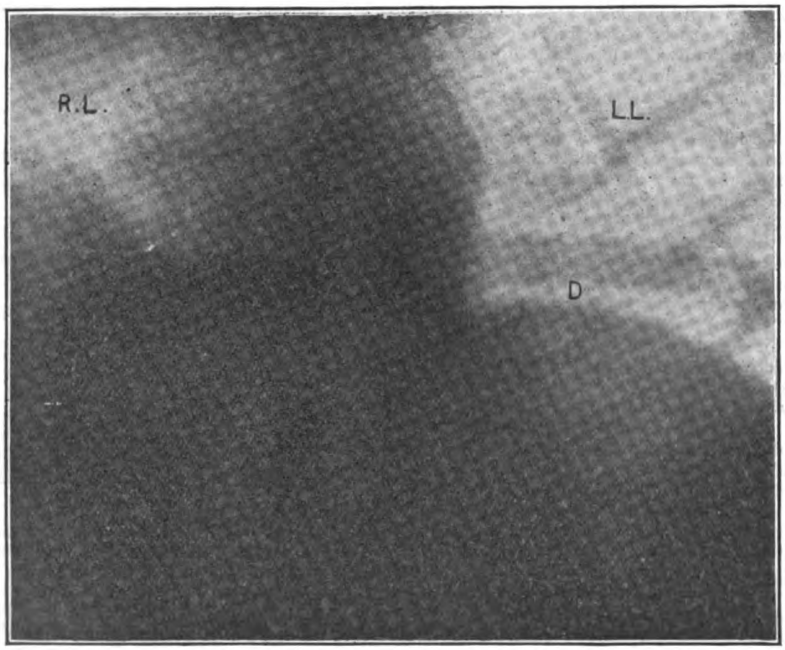
A similar specimen with an aneurysm of the descending aorta; laid open, this is seen to lie on the posterior surface of the left bronchus which it compresses.

Sometimes, however, before the bronchus is completely occluded the lung will become over-distended, there will be a hyper-resonant note, and the distended lung may displace the heart and push down the diaphragm. That this condition may result has been almost entirely overlooked by authors, and no reference is made to it in the text-books. Yet over-distension we know not infrequently results if the respiration is vigorous, when there is laryngeal obstruction in diphtheria, in tracheal obstruction from an enlarged thyroid, thymus, or aneurysm, in asthma with spasm and therefore, with stenosis of the smaller bronchi, and in acute bronchitis and bronchiolitis.

It is also what we might expect. With inspiration the chest expands and the surface of the lung closely attached to it by capillary action follows, and the air is sucked past the obstruction as the lung attempts to open. With expiration there is a contraction of the lung due to its elasticity, which is feeble but sufficient for ordinary purposes. This drives the air from the smaller to the larger bronchi, because the pressure in the former is the greater. When forcible expiration is applied, the bronchi as well as the lung tissue are compressed with an equal pressure; if there is no obstruction the air passes on and the pressure therefore falls in the larger bronchi. When an obstruction exists, however, this mechanism fails, the air has greater difficulty in escaping than it had in entering, and the lung becomes over-distended. The pressure may be so much raised that the diaphragm may be displaced two inches and the heart pushed out of position.

This condition gradually develops and persists for a certain time, but by degrees the bronchi fill with secretion, thus increasing the difficulties of the ingress of air, and as the contained air is not replaced, and is subjected to high pressure, it becomes absorbed by the pulmonary blood, while the lung becomes solid, airless, and dull on percussion. Lichtheim has shown experimentally that when the bronchus is completely occluded this airless condition develops almost at once.

FIG. 3.



Skiagram of the chest taken from the front, showing the greatly over-distended left lung due to pressure on the bronchus by an aneurysm. The left lung is over-transparent, the diaphragm is pushed down, and the heart is pushed over to the right. R.L., Right lung. L.L., Left lung. D, Upper edge of diaphragm on left side.

In six of the cases the symptoms were so suggestive of pneumothorax that this diagnosis was more than once suggested.

This possibility of over-distension as a result of bronchial obstruction has been so far overlooked by all authors that the only definite recognition of the condition I have noted is by the late Dr. Pearson Irvine, who, in the Pathological Transactions for 1878, recorded a case of aneurysm pressing on a bronchus in which the lung was larger than normal, although fibroid and bronchiectasic; he came to the conclusion that the result of the pressure had been first to over-distend the lung, that then secretion had accumulated in the bronchi, and the air had been absorbed, while fibrosis and bronchiectasis had resulted from the greatly increased tension, which had compressed the blood-vessels and impaired

the nutrition of the tissues. C. Jacobsohn has also more than once noted that the position of the dulness produced by a growth at the root of the lung may vary with respiration owing to the over-distension of the affected lung, which is best shown by the X rays.

CASE 1. *Saccular thoracic aneurysm compressing the left bronchus and producing an over-distended lung.*—By some it was thought that the case was one of pneumothorax. The patient was a man, aged 29 years, admitted in November, 1905. He had been in the army and had had syphilis. Cough had been present for a year and had been worse for the last three months, with dyspnœa and pain in the left chest. He had no great distress while in bed; the left chest moved badly; there was no tactile vocal fremitus, and no voice nor breath sounds on the left side. On percussion, the note was hyper-resonant. There was no cardiac dulness on the left, and on the right there was dulness, which varied with respiration, extending from the fourth rib out to beyond the right nipple and down to the liver. There was marked epigastric pulsation, the heart sounds were faint, and no bruit was audible. There was compensatory breathing over the right chest. There was considerable uncertainty with regard to the diagnosis, but it was thought that most probably the condition was due to an aneurysm pressing on the left bronchus. The patient was examined with the X rays. The whole of the left side of the chest was remarkably transparent compared with the right; no foreign body was visible; the heart was displaced nearly 2 inches to the right of the sternum with deep inspiration, and back again behind the sternum with expiration. The diaphragm was depressed on the left side, but no trace of any aneurysm could be seen. (Fig. 3.) The temperature was normal and the pulse 72. There were no stridor, no evidence of any syphilitic ulceration of the trachea and bronchi, and no expectoration. It was elicited that three

FIG. 4.

The bronchi laid open from behind. A, Small saccular aneurysm can be seen opening into the descending aorta, compressing and almost occluding the left bronchus, through which a glass rod, A, has been passed.

months previously a crust of bread had gone "the wrong way," but had this passed into the bronchus there would have been evidence before now of septic pneumonia. The extreme translucency and distension of the left chest, with the absence of any change in the aorta, threw a doubt on the diagnosis of aneurysm, and it was thought that a possible explanation of such marked translucency might be a pneumothorax, although no bruit-d'airain could be elicited, and there was no evidence on the screen of a lung compressed by air. The left axilla was explored with a Southey's tube, but no air escaped. The result of this exploration was to produce an acute attack of pleurisy, and he felt very ill for some time. His temperature two days afterwards was 99° F., and on the next day 101·6°, with a pulse of 112 and intense pain. The temperature did not reach the normal again for nine days.

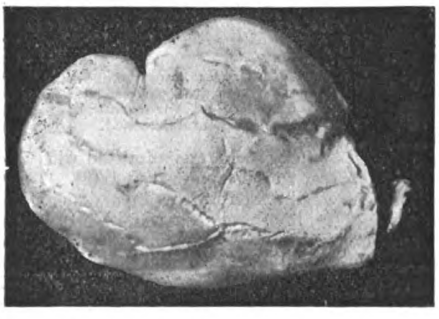
In December the patient was tested with tuberculin with a negative result. Later his opsonic index to tubercle was 0·38. As the condition still remained obscure, the chest was again explored in December with a negative result, except that there was again a sharp attack of pleurisy with pyrexia which lasted for ten days, when the condition again quieted down. At the end of December, 1906, there was an impairment of resonance developing at the left base; there were still an absence of air-entry, diminished tactile vocal fremitus and voice sounds. He now developed pain, with sweating at night, cough, and expectoration, and at the apex behind

FIG. 5.

A section of the corresponding lung showing the reduced size of the lung with fibrosis and bronchiectasis, which has resulted. The fibrous trabeculæ stand out, and there is in addition a destructiv ecavitation in the posterior part of the lower lobe.

there were distant breath sounds. A somewhat tympanitic note was noticed near the cardiac area. No tubercle bacilli could be found. During the next month or two he had a large amount of muco-purulent expectoration which was not foul. In February he began to develop slight clubbing of the fingers, and a rub was audible over the left chest. On Feb. 27th he had a rigor with a temperature of 105° and a leucocytosis of 33,700. He had a sharp attack of pleurisy lasting for ten days. In March the impulse of the heart had returned to the left side of the sternum. There were consonating râles at the back of the left lung and not much difference between the note on the two sides.

FIG. 6.



A piece of over-distended lung showing lines of interstitial emphysema.

It was at first difficult to explain the attacks of severe pleurisy which followed both attempts at exploration. It was clear afterwards that infective fluid from the distended bronchi had inoculated the pleura, as doubtless owing to the great pressure under which it was retained some leaked into the pleura from the puncture. Had the lung not been under tension it would probably not have set up any infection. The

obstruction to the bronchus was not complete as there was expectoration, although the movement was so feeble that we could not hear air being sucked up to the surface of the lung. It is noticeable that so long as the lung remained quiet, and before it became fibroid, so that the contents did not pass into the lymphatics but remained in the lung, or were expectorated, the patient remained free from fever, yet the faintest trace in the pleura set up a violent reaction.

His symptoms gradually quieted down, and he continued fairly well. I did not see him from April, 1906, to the end of February, 1907, when he was seized with general pains, pyrexia, and troublesome cough. Soon the expectoration became abundant and extremely foul, so that he vomited frequently. On readmission he was very ill and feeble. The left chest was contracted; the movement was deficient; there was an impaired note at the apex and below, and also in the axilla it was dull. Over the upper spaces the air-entry was deficient and broncho-vesicular; below it was lost. Numerous râles were audible, with compensatory breathing on the right side. The pulse was irregular, 108; the impulse was dragged three-quarters of an inch outside the nipple by contraction of the lung. A diagnosis of gangrene of the lung was made. The condition proved fatal on the 26th, three days after admission

Post mortem a saccular aneurysm opening just at the commencement of the descending aorta had compressed the left bronchus and produced a condition of fibrosis of the whole of the left lung with recent septic broncho-pneumonia. (Fig. 4.) There was bronchiectasis of the tubes beyond the compression, with cavitation due to recent putrefactive infection, which was most marked in the posterior part of the lower lobe. (Fig. 5.)

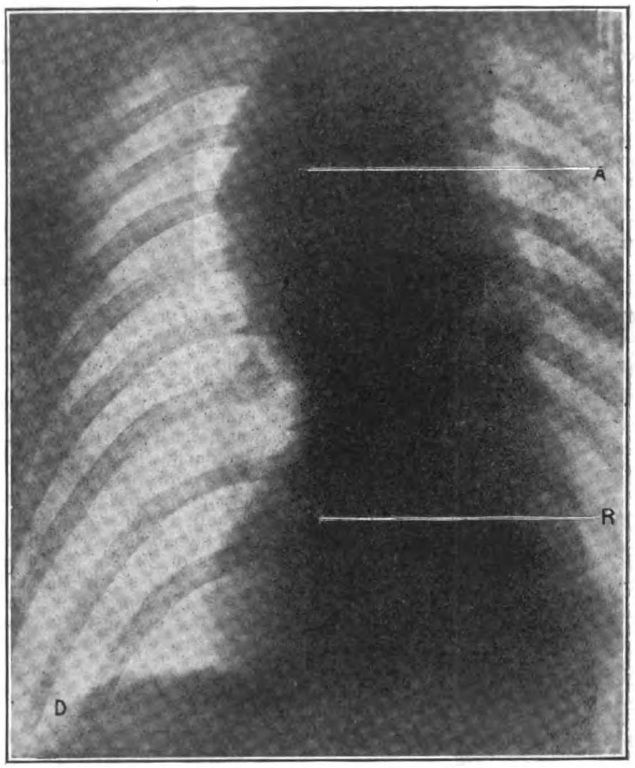
Until I saw this case I was quite unaware that a partial compression of a bronchus was capable of producing an over-distended lung, which might be confused with pneumothorax.

CASE 2.—The patient was a man, aged 30 years, who was admitted with bronchitis and intense dyspnœa, which soon proved fatal. The trachea was found to be compressed by an aneurysm of the transverse aorta. The lung was enormously over-distended (Fig. 6) and had ruptured, producing interlobular emphysema, as shown by the lines of the interlobular septa which, when fresh, were distended with air, but now are collapsed and empty.

I am indebted to Dr. E. W. Martin for the two following skiagrams which excellently illustrate my contention. Fig. 7 represents a chest taken from the back. The left side is uniformly transparent; the intercostal spaces are wider than on the right. The diaphragm is flattened and displaced downwards and the heart to the right. The aneurysmal dilatation of the arch, with the marked excursion of pulsation, is well shown. There were well-marked signs of an aneurysm compressing the left bronchus. The condition was diagnosed on account of this skiagram as pneumothorax with aneurysm, but the appearance is really due to an over-distended lung. This will be at once apparent if we contrast it with an equally good skiagram of a pneumothorax, also taken so long ago as 1902 by him. (Fig. 8.) Here the air space is more transparent than was the over-distended lung, but the lung, shrunk up near its root, is obvious, due to a ruptured phthisical cavity above this, which was wanting in the other picture. The heart and diaphragm are more displaced, and the latter has a much sharper outline.

[Since the lecture Dr. Martin has been able to obtain me the following notes of the case, which was in Victoria Park Hospital in 1902. There was pulsation over the upper part of the sternum, with a dull note. The note over the left chest was resonant; no cardiac dulness; apex beat was one inch to the left of the sternum in the fifth space; the heart sounds were very feeble, but best heard on the right of the sternum; extremely feeble breath sounds all over the left chest, it hardly moves at all, and the whole chest, back and front, is larger than the right. An exploring syringe was introduced into the seventh space on the left side, and connected with a tube under water, when about 30 bubbles of air escaped. The condition at that time was considered to be one of pneumothorax and aneurysm. The escape of the bubbles of air naturally suggested this; the skiagram, however, is definitely that of an over-distended lung, and I am supported in this view by Dr. Hugh Walsham. The air must therefore have escaped from the interior of the lung itself, and the explanation is that it must have been retained under great pressure, which is also indicated by the condition of the lung.]

FIG. 7.



A skiagram of chest taken from behind showing over distended, abnormally transparent left lung due to aneurysm compressing left bronchus. A, Aneurysm. R, Heart displaced to right. D, Left diaphragm displaced and flattened.

CASE 3. *Aneurysm compressing the left bronchus. Signs at one time suggesting pneumothorax.*—The patient was a man, aged 39 years. In October, 1906, there was pain behind the sternum. The physical signs on admission left it doubtful whether he had pneumothorax or an obstruction of the left bronchus. There were cough and stridor, there was deficient movement of the left side, but it looked enlarged. Some hyper-resonance was present. There were no tactile vocal fremitus and no breath sounds, and the voice sounds were diminished; on the right side there was compensatory breathing. The heart sounds were not well heard on the left side, but were better than normal on the right side. On Dec. 15th a skiagram showed slightly increased opacity in the region of the aorta. On Jan. 7th there was no dulness; no breath sounds were audible over the left chest. In February breathing was audible behind in the upper part, but the cardiac impulse was not palpable. In March there was a better entry of air into the left lung with a few râles. The impulse was in the sixth space one inch outside the nipple. On March 14th the left base was becoming dull; when the patient went out in May the left chest had an impaired note with deficient breath sounds. Fatal hæmoptysis occurred a few weeks later.

CASE 4. *Saccular aneurysm compressing and eroding the left bronchus; high-pitched note over the left chest; signs suggestive of pneumothorax; fibrosis with bronchiectasis.*—The patient, a man, aged 38 years, had had cough and pain in the chest for six months. The left chest was *less flattened* than the right, there was defective movement, and a *high-pitched note* all over on the left side. There was no cardiac dulness and no dulness in the axilla. Voice sounds were deficient and breath sounds absent. Behind, the *left chest bulged more* than on the right; there were diminished tactile vocal fremitus and voice sounds. The chest circumference was 36 inches and the expansion three-quarters of an inch. The heart sounds were indistinct, but were best heard behind the sternum and to the right. Diagnosis: growth or pneumothorax. The temperature oscillated between 102° F. and normal while the patient was in the hospital. On April 26th, 1902, the chest was *smaller*, being only 34 inches, and there was a slightly impaired note over the præcordium. Fatal hæmoptysis occurred.

Post mortem a saccular aneurysm was found opening into and compressing the left bronchus. There was a septic pneumonia of the left lower lobe, with fibrosis and bronchiectasis.

CASE 5. *Aneurysm of the descending aorta opening into the left bronchus. ? Pneumothorax or aneurysm.*—The patient, a man, aged 38 years, had dyspnœa and pain with impaired movement and absence of breath sounds on the left side; there was a hyper-resonant note and the heart was displaced to the right. On Sept. 20th, 1897, there was some dulness at the left base. Fatal hæmoptysis occurred while the physician was preparing to explore. ? Pneumothorax or aneurysm.

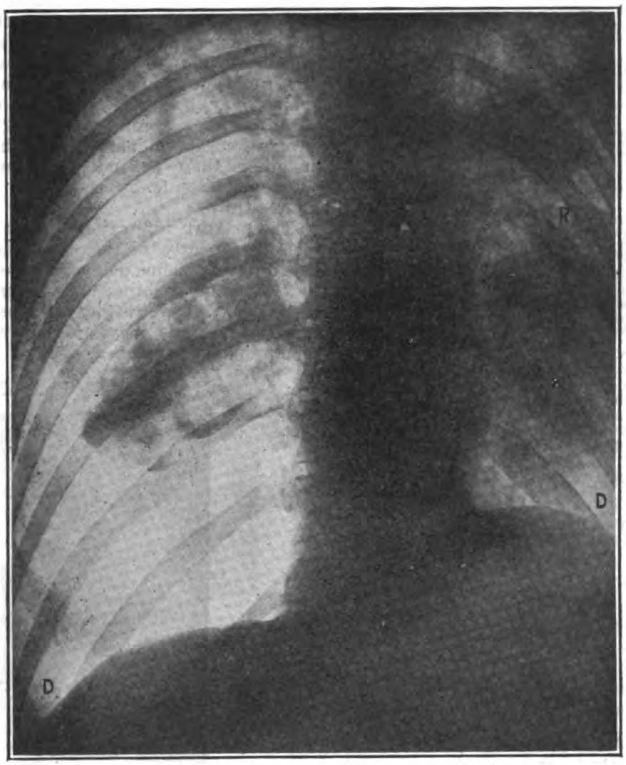
Post mortem there was an aneurysm at the commencement of the descending aorta, which had opened into the left bronchus near the point of bifurcation. The lungs were mottled with blood that had been sucked in; the edges were emphysematous. The lower lobe was solid, mottled grey-green, with a quantity of odourless pus in the tubes.

CASE 6. *Aneurysm compressing the left bronchus; left lung over-distended, the signs suggesting pneumothorax.*—The patient had a well-formed emphysematous chest, the left side being *more bulky and larger* than the right and moving scarcely at all. No apex beat could be felt; there was a slight pulsation in the third right space 1½ inches from the edge of the sternum. There was a *hyper-resonant note* in the left chest obliterating the cardiac and the splenic dulness. Breath sounds were absent on the left side and very faint at the apex; there were no tactile vocal fremitus, no voice sounds, and no bruit d'airain. The circumference of the left chest was 18 inches; at the level of the right nipple 17½ inches; at the level of the left 17¾ inches. There was no movement on the left side. Diagnosis: pneumothorax due probably to the rupture of a phthisical cavity. The temperature was remittent. Later the note at the left base was slightly impaired.

The following is a remarkable instance in which the patient survived 20 months after the first severe hæmorrhage from the erosion of the aneurysm into the bronchus, the opening being probably a valvular one, which he was able to close by retracting his head and thus diminishing the antero-posterior diameter of his chest.

CASE 7. *Aneurysms of the aorta, one compressing the left bronchus, and another the trachea; recurrent hæmoptysis for 20 months before death.*—The patient, a man, aged 50, under the care of Dr. M. Parry-Jones of Derby, had four years ago dyspnœa on exertion, when an aneurysm was suspected; 20 months before death hæmoptysis (one pint) occurred; the blood came more rapidly when he leaned forwards, and was checked when he drew back his head. He also noticed that turning his head to the right reduced the volume of his right pulse. Gradually a slight pulsation with a diastolic jog developed beneath the left clavicle. There were diminution of breath and voice sounds on the left side, but no dulness. There were four further attacks of hæmoptysis amounting to several ounces during the next year, but by reducing his fluid to 13 ounces and keeping quiet he kept them in abeyance.

FIG. 8.



Complete pneumothorax left side; heart displaced in front of sternum. D, D, Diaphragm displaced and flattened. R, Right lung subject of caseous tubercle. Note the wider intercostal spaces on the left side.

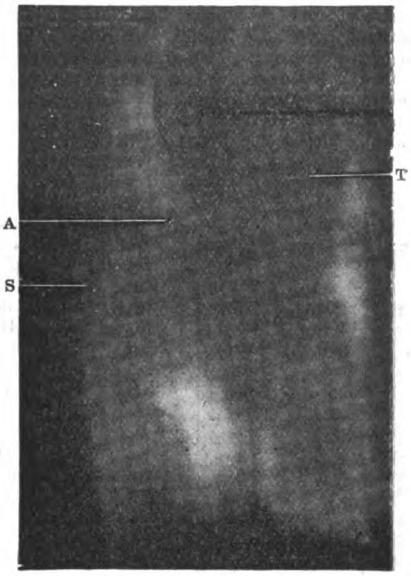
Three dilatations were found involving respectively the ascending, transverse, and descending portions of the arch. The opening into the air tubes was closed up. There was no great bronchiectasis. It is remarkable he should have survived the first rupture for 20 months.

CASE 8. *Saccular aneurysm of the descending aorta which compressed the left bronchus and the œsophagus.*—The patient, a man, aged 49, under the care of Dr. W. P. Morgan of Seaford, had had pain for a year in the left chest and cough for three months. Recently there had been expectoration in the morning streaked with blood. He had dysphagia, liquid food frequently coming back again into his mouth after some little time if he swallowed. Dyspnœa ensued on exertion; there was defective movement on the left side, with distension of the veins on that side of the chest. There was resonance with deficient breath sounds over the left side, and a very marked delay (almost one second) in the onset of inspiration, which was quite noticeable when a double stethoscope was used. There were deficient voice sounds and the tactile vocal fremitus note was very slightly impaired, if at all. (Fig. 9.)

The features especially associated with bronchial pressure from aneurysm may be summed up as follows: 1. The left bronchus is involved six times as often as the right. 2. The right is very rarely eroded. 3. Resonance with silence. There are deficient or absent breath sounds over the left lung with a resonant or hyper-resonant lung. This does not necessarily indicate more than a partial occlusion of the bronchus, and occasionally in an early stage the left lung may be over-distended and be too transparent to X rays. The condition has then to be diagnosed from pneumothorax. 4. With X rays dilatation of the aortic arch can generally be detected as the disease of the wall is generally multiple and diffuse. The local aneurysm often is best shown in a

view in the half-turned position with the patient sitting up. The deficient and delayed movement of the lung, the alteration in its density, and the abnormal position and movement of the diaphragm are usually obvious. Occasionally no local aneurysm nor yielding of the aorta can be detected. 5. Later, the development of an impaired note rather than complete dulness, with gradual development of bronchiectasis. It is remarkable how the amount of change which develops is always under-estimated owing to the breath

FIG. 9.



A skiagram of an oblique view, showing an œsophagus with its upper part distended with bismuth and milk. The spine S lies to the left, and the shadow of a saccular aneurysm A extending up to it can be seen compressing the œsophagus; below this point a linear trickle of bismuth alone passes. The shadow extends higher than the point of compression. T is the thoracic aorta.

sounds being absent or feeble. 6. Absence of pleuritic effusion. 7. Retardation of the onset of inspiration on the affected side. 8. In nearly half the cases more or less hæmoptysis. Pain with dyspnœa on exertion are very constant symptoms.

As soon as the mucous membrane ulcerates the liability of the contents of the bronchi to become freshly infected is greatly increased, as the spot is very apt to become a nidus for organisms itself. Hence necrotic changes in the lung occur more often when the tube is ulcerated than when it is only compressed, just as primary growths in the bronchus are especially associated with gangrene.

MALIGNANT DISEASE (55 CASES).

The growth may originate (1) in the bronchus, (2) in the glands at the root of the lung, (3) it may be a secondary deposit in the glands at the root of the lung and grow into it along the bronchus, and (4) as an epithelioma of the œsophagus ultimately invading the bronchus.

1. Primary growth in a bronchus is rare (8); in four cases it started in the right and in an equal number in the left. The growth is generally a columnar-celled carcinoma —at least four-fifths of cases of primary cancer of the lung start in the bronchial mucous membrane. Most of the cases came under observation for pleuritic effusion, which not infrequently required tapping more than once. In half the cases gangrene of the lung developed. In some a fragment of growth was expectorated, and thereby its malignant nature determined. There are generally pain and pressure signs.

2. Growth in the glands (26 cases) half affecting each bronchus. Two were described as lymphadenoma, but as they eroded the bronchus it is more probable that they also were sarcomatous.

3. Secondary deposits in the glands at the root of the lung (6 cases); the growth compressed the bronchus and invaded the lung.

4. Epithelioma of the œsophagus (16 cases). The two bronchi are invaded with equal frequency. In four they were only compressed; in the others the growth had fungated in. With epithelioma the pulmonary condition rapidly proves fatal, with a septic pneumonia, abscess formation, or gangrene. Bronchiectasis and fibrosis have not time to develop. The rapidly fatal changes are due to the infection with food from the communication with the œsophagus. The food is doubtless often squeezed in by the contraction of the œsophagus owing to the obstruction of its tube beyond by growth. In one case a deposit in a gland led to compression of the lower branch of the left bronchus with the development of bronchiectasis beyond. A troublesome paroxysmal cough, pyrexia, and pain are the indications of the onset of trouble in the lung to which foul expectoration is soon added.

The special features of malignant disease are the frequency with which pleuritic effusion and also gangrene develop (more than half). The effusion is an early sign, and both this and the collapse of the lung, as well as the growth itself, all give dulness which is often quite marked. It has been pointed out by writers that the physical signs given by the changes in the lung and the pleura are obvious at an early stage and tend to obscure the evidence of the growth itself. In many the pulmonary artery is also compressed and may be occluded, and this much more frequently so than by an aneurysm; hence the rapid development of extensive patches of gangrene which may lead to the development of large cavities, often without fibroid thickening of the wall. In a small proportion fibroid changes in the lung are well marked; in others there has not been time for them to take place. Bronchiectasis is by no means always present, but only in one-third.

The massive infiltration of the root of the lung occludes not infrequently the lymphatics and blood-vessels as well as the bronchi: hence œdema of the pulmonary tissue tends to develop and the bronchi to become more rapidly overfull of secretion. Stridor is not infrequently present, especially on exertion, but is most marked when the growth has also compressed the trachea.

FIG. 10.

The left lung presents a large cavity the anterior wall of which was torn on removal. When fresh the walls were flocculent, but unfortunately in preparing the specimen they have become smooth. A probe A can be seen projecting through the remains of the bronchus; the pulmonary artery was also involved.

CASE 9. *Squamous epithelioma of root of the lung with destructive disease of the lung beyond.*—The patient was a man, aged 65 years, who for 20 months expectorated material of the colour of strawberries and cream, at one time amounting to a pint a day. The only physical signs owing to the occlusion of the bronchus were deficient breath sounds over the left base.

Post mortem the left lower lobe of the lung was excavated out into a cavity 4½ inches across, with necrotic, flocculent walls; there were numerous dilated bronchi in the rest of the lobe with fibrosis. The bronchus and pulmonary artery were compressed, being embedded in the mass of growth. The

primary seat was not determined as the post-mortem examination was limited to the thorax (Fig. 10).

This specimen is of interest as showing the early formation of a single large cavity from destructive changes from necrosis, and in this instance without any foul secondary putrefactive changes. It illustrates the fact that the physical signs of a large cavity over 4 inches across may be almost *nil* when there is stenosis of the bronchus, owing to the absence of any breath sounds. Contrast it with the extensive fibrosis and the usual absence of large cavities which result when the pressure is due to an aneurysm.

As another example showing how a mass of sarcoma growing into the root of the lung associated with occlusion of the pulmonary artery tends to form large cavities, in addition to a general fibrosis of the lung with moderate dilatation of the tubes, the following may be quoted.

CASE 10.—The patient, a woman, aged 38 years, died a few hours after admission. At the inspection the left lung was healthy. A section has been made of the right lung, with the mass of growth at its root. A rod has been passed through the much-constricted bronchus. The pulmonary artery except for a small branch was occluded. Almost the whole of the lower lobe was excavated out into a cavity. There were smaller cavities in the lower part of the upper and middle lobes with general dilatation of the tubes in a dense fibroid tissue. (Fig. 11.)

FIG. 11.

CASE 11. *Primary cancer of bronchus; expectoration of a nodule of growth; duration of symptoms three and a half years; fibrosis with bronchiectasis.*—The patient, a man, aged 40 years, first noticed some wheeziness in September, 1901, and during the year 1902 he became short of breath on exertion; he lost half a stone in weight, there was an ounce of muco-purulent secretion daily, and on exertion or deep breathing there was some stridor. The wheeze or musical whistle with expiration was loudest when he lay on his left side. He had no pain. In October there were deficient breath sounds with a slight squeak, and deficient voice and tactile vocal fremitus over the left side, with dulness in front at the apex. There was similar deficiency in breath sounds at the apex; the base was fairly normal; the right side was quite normal. With a skiagram there was a slight opacity at the left apex, but less than is often met with in growth, although the evidence pointed in that direction. There was no evidence of aneurysm. He was subject to attacks of pyrexia with an increase in the expectoration. He continued to lose weight, and towards the end of the year there was a pleuritic rub. He had a few slight rigors. In December the dyspnœa had increased considerably, and he was very frequently sick unless very careful with his diet. A rough, blowing systolic bruit developed to the left and above the heart; the resonance became more impaired above, and the breathing indeterminate, with an increase in the voice sounds. The impulse of the heart was pulled upwards and outwards. There was pulsation over the affected area at the left apex which apparently was transmitted from the heart and was not due to an aneurysm. The diaphragm was as high as the fifth rib in the axilla. During the year 1903 he was able to get about if he moved slowly. Expectoration was limited to half an ounce; it was slightly blood-stained, but never offensive. The amount of blood varied somewhat.

The patient continued fairly well until May, 1904, when he had an attack of pericarditis which lasted for six weeks. In December, 1904, he coughed up a piece of tissue an inch long and three-eighths of an inch in diameter, which came away quite easily with only a little hæmorrhage. On microscopical examination this was found to be a portion of glandular carcinoma composed of tortuous columns of columnar cells; there were also cells in alveoli which communicated with these columns. Another nodule was expectorated in the following March. On April 18th, 1905, I again saw him with Dr. R. P. Cockburn of Ealing. The patient had got worse during the last six months, frequently expectorating as much as an ounce or two of blood. The dyspnœa had increased. He was practically confined to his bed. For a long time he was unable to lie on his left side, and latterly only on his right side. There was pulsation as high as the third space above the nipple, to the left of the heart; there were a noisy, wheezy stridor and noisy expectoration. We came to the conclusion that a nodule of the growth had fungated through, probably into the trachea, and it was a question whether there was not originally a foreign body in the left bronchus which was the starting point of his trouble. He died the next day.

On post-mortem examination the right lung was found over-distended but otherwise normal; there was an adherent pericardium. There was a mass of growth at the root of the left lung in which the bronchus and vessels were embedded. No foreign body was found; the left lung was extremely contracted. The upper lobe was reduced to a mass about two inches across and seven inches long, riddled with small bronchiectasic cavities, while the lower lobe was converted into a very dense fibroid mass no bigger than the lung of a child of six and was also riddled with cavities.

COMPRESSION BY INFLAMED GLANDS (12 CASES).

The 12 cases were: enlarged glands 7, suppurating and opening into a bronchus 5. These cases occur mainly in infants in whom the glands are active and the antero-posterior diameter of the thorax is so small that a mass of glands at the bifurcation of the trachea may lead to serious symptoms, but especially when they press on the trachea. They less often compress the bronchi seriously, and this generally only occurs when there are enlarged glands on each side of the bronchus, which accounts for the comparatively few cases in which enlarged caseous glands give rise to pressure symptoms. The cases of pressure on the trachea are apt to be looked upon as due to laryngeal diphtheria, but the absence of movement of the larynx is of diagnostic importance. Their enlargement may be made out by dulness internal to root of one scapula, by the opacity shown by X rays, by the absence of breath sounds on one side, and by a venous hum over the sternum on retracting the head, although I have only been able to elicit this sign three or four times.

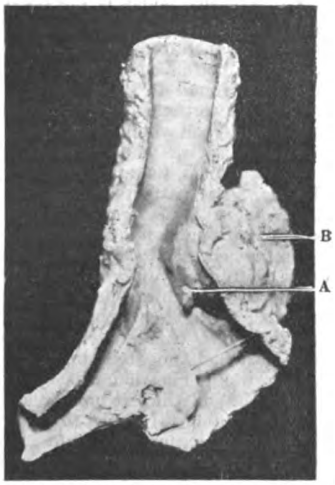
When a suppurating gland breaks into a bronchus the child has severe dyspnœa with violent paroxysms of cough, and may bring up some purulent secretion, while there is soon an active development in the lung beyond of fresh physical signs. When in a child there are evidences that a bronchus is compressed it is far more likely to be due to an enlarged caseous gland than to a foreign body, unless there is a definite history of sudden onset of symptoms after swallowing something. Most of the cases due to caseous glands are complicated with phthisis; less than half of them are diagnosed; but X rays make it much easier to do so now than formerly.

In 3 cases abscesses opened into a bronchus: (1) empyema, right side; (2) suppurating bronchial glands secondary to suppurative pylephlebitis; and (3) abscess communicating with the œsophagus and gangrenous cavity in the lung.

CASE 12. *Compression of trachea and right bronchus by enlarged caseous gland.*—A child, aged 2 years, was admitted to hospital in 1910 with dyspnœa and stridor, which was supposed to be due to laryngeal diphtheria. On examination it was found that there were deficient breath sounds over the right side, with impaired resonance. The larynx did not move with respiration, and compression of the root of the right lung by caseous glands was diagnosed. The child died a few hours later. A large caseous gland compressed the

trachea in front, just above the bifurcation. Another large gland between the bronchi was softening; the right lung was collapsed and airless; the left lung was normal (Fig. 12).

FIG. 12.



A trachea and bronchi laid open from behind showing the opening (A) into the right bronchus of a caseous gland (B) which had suppurated.

DILATED LEFT AURICLE.

A cause of pressure sufficient sometimes to cause physical signs during life but rarely to present much evidence post mortem is a dilated left auricle due to mitral stenosis, to which attention was directed many years ago by Dr. Wilkinson King.

CASE 13. *Pressure on left bronchus by dilated left auricle.*—In 1888 a woman, aged 50 years, was seen suffering from mitral stenosis with a greatly dilated left auricle. At the inspection there was also a softening ante-mortem clot in the appendix. The left base was airless and sank in water; it could be inflated less than the right one, which was also œdematous and engorged. Both were deficient in air. The left bronchus was markedly compressed by the dilated left auricle.

FIBROUS BRONCHIOLITIS DUE TO IRRITANT GASES.

Inhalation of irritant gases is a well-known cause of intense dyspnœa and bronchitis, not infrequently fatal, with a greatly over-distended lung, of which we have had examples from time to time. Fraenkel has shown that this condition may be due to an acute fibrous obliterating bronchiolitis, which may develop within a fortnight. He has recorded cases after inhalation of the fumes of chlorine, of cow hair and lime dust, and after calcium chloride dust.

A man after inhaling chlorine had intense dyspnœa, which passed off but returned next day, when he was cyanosed, with an extremely distended lung and fine crepitations. The condition again cleared up, to return again after a week, when he died. Widespread fibrous peribronchial inflammation was found round the smaller bronchioles, with necrosis of the lining epithelium, producing constriction of the tubes with dilatation beyond. Schmorles has described a similar condition in the broncho-pneumonia of measles, with obliteration of the bronchioles. The ingravescent cyanosis with dyspnœa and a rapid and great increase in the size of the lung are the essential points, especially when there has been exposure to irritant gases.

STENOSIS OF THE BRONCHI FROM SYPHILIS.

Out of seven cases, two were due to gummata pressing on a bronchus. The way in which the tubes dilate under violent inspiratory efforts with bronchial obstruction is well shown in a case (No. 14) of a man, aged 64 years, where a gumma pressed on the upper division of the right bronchus. The upper and middle lobes were over-distended, the lower lobe was airless from compression with five pints of fluid. The illness was rapidly fatal. The second (No. 15) was a chronic case with a gumma compressing the superior cava and the right bronchus; the bronchi beyond were dilated up to their extremity and their walls were thickened; the lung was solid. There was extensive pleuritic effusion into the left side secondary to the pressure on the cava.

There were five cases of cicatricial stenosis of the bronchus secondary to syphilitic ulceration, and the patients were all under the age of 40. In two the larynx was also involved, in four the trachea, and in four there was bronchiectasis. Stridor is generally present, but often is independent of the bronchial lesion. There are generally other signs of syphilis present, so that an accurate diagnosis can be made in the majority of cases.

CASE 16.—The patient was a man, aged 38 years; he was admitted with extreme laryngeal stridor and fixed cords due to laryngeal paralysis requiring tracheotomy.

Post mortem, the left lower lobe was collapsed. There was syphilitic stenosis of the right bronchus, with scars on the trachea; the right lung was fibroid, with a dense gummatous fibrous mass involving the root of the right lung and the vagus. In spite of the vagus being involved there was no destructive disease of the lung. Sir W. Gull at one time suggested that the destructive lung disease associated with aneurysm was due to implication of the vagus (Fig. 13).

FIG. 13.

A trachea, with part of the right lung, showing syphilitic stenosis of the right bronchus, with scars on the trachea, a fibroid right lung, with dense gummatous fibrosis involving the root of the lung and the vagus.

FOREIGN BODIES.

The result of the introduction of a foreign body into a bronchus depends upon whether the bronchus is partially or completely occluded, on the vigour of respiration, and on whether the body is an organic one which will readily putrefy.

Our knowledge of the changes which result largely depend on the experiments of Lichtheim in 1878, who introduced laminaria tents into the bronchi of rabbits, and also in others removed portions of the third and fourth left ribs, ligatured the bronchus, and studied the results. He showed that when the plug completely occluded the bronchus the lung quickly collapsed and became airless. There was at once an intense dyspnœa which gradually quieted down. In many cases the animals died within 24 with pneumothorax of the opposite side from rupture of an enormously over-distended lung; in others the over-distension of the sound lung had stretched the capillaries and made them useless, equally producing a fatal result. Pneumothorax does not occur from this cause in human beings. The affected lung beyond the obstruction was of a dull brown-red colour, with the consistency of muscle. With early death the bronchi were empty, but became filled with a thick white mucoid secretion whenever the animal did not die too soon. When he ligatured the bronchus alone the same result was produced. He found that when the animal was made to breathe oxygen absorption was much quicker, in some

cases being under an hour; CO_2 absorption was less rapid but much more so than when it breathed air. When the pulmonary artery was also ligatured absorption was much delayed, showing that the gases were absorbed by the blood circulating in the lung.

When the chest was merely opened and the lung exposed to the air atelectasis took place quickly, but did not if the pulmonary artery was ligatured. This opening of the chest vitiates many of his results, as it prevented any vigorous respiratory movements from taking place. This was well shown by the fact that when the bronchus was ligatured the opposite lung did not become over-distended to the extent it did when the bronchus was blocked by a foreign body. When the hilum of the lung, including the pulmonary artery, was ligatured there was generally no infarct because there had been no suction of the blood owing to the absence of the opening up of the alveoli with inspiration. This affords the explanation of the absence of infarcts in cases of growth at the root of the lung and of aneurysm in which the pulmonary artery had been occluded by pressure. When the animal survived some weeks the lung was fibroid and converted into a sac of dilated tubes, presenting an appearance similar to that of a calculous pyelonephritic kidney.

Partial obstruction of the bronchi has not been thoroughly studied experimentally, and we have still much to learn; the presence of expectoration in amount shows that this is the more usual condition which results from the presence of a foreign body in a bronchus, and I have little doubt that in some cases the lung at first becomes over-distended, and is not always airless and collapsed.

Schuller has shown that it is possible to introduce clean food into the bronchi of rabbits, and if it can disintegrate it will disappear with no change in the lung beyond that of catarrh; when it cannot, fibroid changes with bronchiectasis result. When dirt, however, was mixed with the food gangrene or septic pneumonia resulted.

There have been the following cases: (1) head of barley grass in left bronchus 129 days; (2) pork in right bronchus possibly for six months; (3) wooden top of toy in left bronchus; (4) pea in left bronchus; (5) feather after tracheotomy, in right bronchus, but not cause of death; (6) pipe stem in bronchus after fatal fall down ladder (not cause of death); (7) newspaper in trachea, introduced intentionally; and (8) sponges in trachea, introduced intentionally.

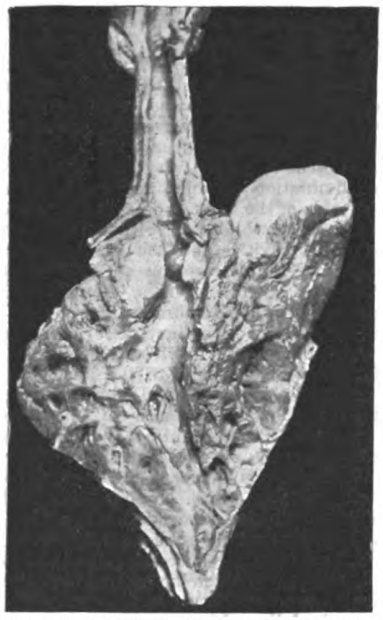
The following case presents many very remarkable features. The boy swallowed a head of barley grass during a paroxysm of coughing and this passed into his left bronchus, where it remained 129 days. He developed within two days after the entrance of the body an acute pneumonia which became gangrenous, and he had an extremely prolonged dangerous illness. Acid-fast bacilli were found on one occasion in the sputum and were assumed to be tubercle bacilli, but he made an excellent recovery as soon as he expectorated the piece of grass. He never reacted specifically to tuberculin. He has maintained perfect health for the five years since and is now strong and well.

It is very rare for anyone to make such an excellent recovery after such extensive mischief in the lung, and it is suggested that the acid-fast bacilli came from the grass as these grasses are said to contain them.

CASE 17. *Ear of barley grass in the left bronchus for 129 days; gangrene of the lung; complete recovery.*—A boy, aged 12 years, while recovering from an attack of whooping-cough, was playing with a head of grass in his mouth, when he was seized with an attack of coughing and the piece of grass disappeared. He tried in vain to make himself sick. On the next day the temperature was 102·8° F., and on July 25th (the following day) Dr. J. E. G. Calverley of Folkestone, under whose care he was, found that the temperature was 105·2°, with a pulse of 100. There was pain in the epigastrium. The entry of air at the left apex in front was deficient. On the 28th there was diminished entry over the same area with diminished movement, but a hyperresonant note. There was tracheal wheezing, conducted over the whole chest as rhonchi. The temperature, respiration, and pulse remained high, and on the 30th the boy had consolidation at the left apex down to the third rib with bronchial breathing and pectoriloquy. The larynx was found to be normal. On August 1st there was profuse epistaxis with a tympanitic note at the left apex in front and down to the level of the fourth rib in the axilla. The entry of air remained deficient at the left apex. He became anæmic from recurrent epistaxis. He then passed under the care of Dr. R. B. Wrightson at Aldeburgh. The temperature gradually dropped to 99°, and the boy was able to get about. The sputum at first was frothy, but later became abundant and muco-purulent, and was said to contain tubercle bacilli. In the middle of September his temperature ran up to 104° and he developed signs of consolidation at the left base. In the upper lobe there was dulness at the apex with signs of a cavity in front in the second and third spaces. There was a marked oscillation of the temperature with very foul breath indicative of gangrene. He was extremely ill for a long time with a very feeble pulse. He took creasote regularly and was well nursed in the open air, so that gradually he recovered his health. No tubercle bacilli could be again detected, and at the end of October he had gained a stone in weight. The sputum was reduced to half an ounce in amount daily and was no longer foul. On Nov. 30th, 129 days after swallowing the grass, he had a fit of coughing and brought up a head of timothy grass 1¼ inches long from the left bronchus. The long awns had broken off from decomposition, and so it was able to pass out again backwards, which had been quite impossible so long as they were intact. There was a gradual retrocession of the signs, but there remained at the apex a deficient resonance, with indeterminate breathing and increased voice sounds; a few moist sounds persisted at the lower part of the lung for some time. In December the opsonic index for tubercle was found to be 0·6 and 0·65 on two occasions. An attempt was made to see whether any acid-fast bacilli could be cultivated from the piece of grass he brought up, but none could be found, although many other organisms were present.

CASE 18. *Pea wedged in lower branch of right bronchus; marked bronchiectasis of corresponding tubes only.*—The patient was a boy, aged three years, admitted with cough and vomiting. He died with empyema and cerebral abscesses a month later. (Fig. 14.)

FIG. 14.



The trachea and right lung showing a pea wedged in the lower bronchus on the right side. The upper lobe of the lung is healthy, but the rest of the lung is densely fibroid and riddled with intercommunicating cavities the result of the obstruction.

CASE 19. *Piece of pork in right bronchus; bronchiectasis; septic pneumonia.*—In 1888 a man, aged 60 years, was admitted. For six months there had been wasting, and for two weeks foul breath. For two days there had been deficient movement of the lung on the right side, pleural rub in the axilla and base, deficient air-entry, râles, with amphoric breathing over the middle lobe.

At the inspection the right lung was fibroid with general bronchiectasis of the main bronchi. Low down was found a

piece of pork ½ × ⅜ inch. There were cavities in the lower lobe. There was acute pneumonia at the lower part of the upper lobe with œdema of the left lung. Had the pork been there for six months?

CASE 20. *Piece of wood in left bronchus; bronchiectasis of both lungs.*—In 1905 a female child, aged 16 months, was admitted. She was well until five weeks before admittance, when she had a cough and dyspnœa. The right lung was resonant on the anterior part in front, but impaired behind. There were crackling râles, bronchial breathing, and pectoriloquy behind.

At the inspection there was advanced fibrosis with bronchiectasis of the right lower, the right middle, and the left lower portions, with a mass of dilated tubes in the midst of the parts of the lung which were fibroid. The *two left upper lobes* were distended; there was recent bronchopneumonia. In the left bronchus just beyond the point of bifurcation there was a smooth piece of wood broken off a toy. It was doubted at the necropsy whether the piece of wood had caused the bronchiectasis, because it was found in the left bronchus and the bronchiectasis was also on the right side, but probably at an earlier stage it was in the right bronchus, and had produced changes on that side and been displaced to the left later.

Although many cases of foreign bodies in the bronchi have been recorded, in but very few has an accurate note been made of the physical signs in the lung in an early stage of the illness. The body generally passes into the right bronchus because it is more vertical and is also slightly larger. The changes are unilateral, serious, and progressive. The following are the most important evidences suggestive of a foreign body in a bronchus, and in any such case a bronchoscope should be passed in order that the condition of the tubes may be determined, and a positive opinion formed. 1. A most important factor in diagnosis, and one which until we had X rays was absolutely essential, is the history of swallowing something immediately before the onset of an acute attack of severe dyspnœa and cough. 2. Not infrequently a whistling or wheezing sound which the patient can localise to one side, varying in quality if the object is not fixed in the bronchus. 3. Great distress, with not infrequently a constricting pain behind the sternum, made worse by movement. 4. Dyspnœa, with varying exacerbations, often intense and made worse by cough, but it may be elicited only by exertion. After a time there may be no distress. 5. Absent or, rarely, very noisy breath sounds with some slight diminution of voice and tactile vocal fremitus limited to one side of the chest. 6. At first resonance on the affected side, soon consolidation with dulness, and, after a time, the signs of cavities and the simulation of phthisis; query occasionally hyper-resonance. The physical signs sometimes vary from time to time. 7. With X rays, the defective movement of the diaphragm and of the thorax, the alteration in the density of the lung, and not infrequently the outline of the foreign body itself, may be clearly made out. 8. Delay in the commencement of inspiration as compared with that on the other side. 9. Defective movement with consequent diminution in the size of the affected side. 10. Violent paroxysmal persistent cough, which is apparently most marked when the object is at the bifurcation, as the sensibility of the mucous membrane is greatest here, as can be noticed when passing a bronchoscope. 11. Early pyrexia, which later becomes hectic, associated with chills. 12. After a short time an expectoration more or less profuse, purulent, often bloody, and later often fœtid. 13. In some there are nausea and vomiting which may be very troublesome. 14. Pneumonia often develops in 48 hours; this may be septic and may be followed by gangrene.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An Extraordinary Comitia was held on Dec. 1st, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair. The President announced that Sir James Sawyer had presented to the College a reproduction of the arms of Harvey. In order to procure the needful information a prolonged research had been necessary, and the thanks of the College were heartily returned to Sir James Sawyer for the gift. A communication was received from the secretary of the Royal College of Surgeons of England, dated Nov. 4th, 1910. The remainder of the proceedings were declared by the President to be secreta Collegii.

THE THEORY AND PRACTICE OF THE TREATMENT OF SYPHILIS WITH EHRLICH'S NEW SPECIFIC "606."[1]

BY JAMES McINTOSH,
GROCERS' RESEARCH SCHOLAR;
AND
PAUL FILDES.

THE demonstration by Hata of the lethal effects of "606" on spirochætes in the case of certain experimental spirochætoses led one of us (J. McI.)[2] to experiment later with it on the Spirochæta obermeieri of relapsing fever. The signal success of these experiments without injury to the animals induced us to follow the example of several eminent continental syphilologists and apply the remedy to syphilis. For this purpose, by the great generosity of Geheimrat Ehrlich, Dr. Bulloch was able to obtain a further supply of "606." We are therefore much indebted to Dr. W. Bulloch for entrusting to us its practical application.

The descriptions of the results of Ehrlich's new arsenical preparation dioxydiamidoarsenobenzol ("606") as a specific cure for syphilis and other diseases due to spirochætæ have been couched in language of admiration, which is unusual in medical literature. Alt, A. Neisser, Schreiber and Hoppe, Iversen, Pick, Duhot, Finger, Wechselmann, Michaelis, and others have all written in praise of this substance as a cure for primary, secondary, tertiary, and congenital syphilis. A. Neisser asserted that "606" was far superior to mercury or any other arsenical compound, while Uhlenhuth has discarded his efficacious mercuric atoxyl in its favour. Several of the above authors have recorded cases in which prolonged mercurial treatment had been followed without success, only to heal rapidly under "606." Such cases can be observed by anyone who has had the opportunity of using this substance. Its remarkable effects are obvious, but, nevertheless, we are of opinion that some recent authors have unduly exaggerated the speed of the natural processes of repair. "606" has, no doubt, a very definite effect upon the tissues apart from syphilis, but it cannot achieve the impossible. Some 12,000 cases have up to now been treated, with 12 deaths, a number of accidents which, occurring as they did in the experimental stage of the drug, may readily be reduced in the future. These cases, or at any rate the great proportion of them, are claimed to have been cured, that is, cured in the strict sense of the word.

In order to guard against any repetition of such disasters as followed the introduction of such potent remedies as tuberculin and atoxyl, Ehrlich determined, even in the face of criticism, to give the preparation only to individuals working in recognised laboratories, where his directions could be cautiously carried out. Thus, in the space of a few months, by means of a lavish supply of material, the first epoch, as Ehrlich himself says, has been successfully passed. The results and method of application are for the most part known. There remains the question of *permanency* only.

The Principles Underlying Chemotherapeutics and "606."

Dioxydiamidoarsenobenzol is a substitution product of atoxyl, the great feature of this new preparation of arsenic lying in the fact that the quantity required as a therapeutic dose is only a small fraction of that which can be given without toxic results following. This preparation, like several of the other substitution products of atoxyl, is the outcome of elaborate researches on the part of Professor Ehrlich and his co-worker Dr. Bertheim. The preparation of such products became comparatively simple after they had shown that atoxyl was sodium paramidophenylarsenic acid, and not sodium metaarsenious acid anilid, or, in other words, that the amido radicle was not bound up with the arsenic directly. In this way, mainly by substitution and reduction, most of the new compounds, such as acetylatoxyl, paramidophenylarsenoxyd, arsenophenylglycin, &c., have been obtained. The following graphic formulæ give the steps, according to Ehrlich, by which "606" may be obtained

[1] From the Bacteriological Laboratory, London Hospital.
[2] THE LANCET, Sept. 3rd, 1910, p. 713.

from atoxyl. Atoxyl, as stated above, is the sodium salt of para-amidophenylarsenic acid, of which a formula is shown in Fig. 1:—

FIG. 1.

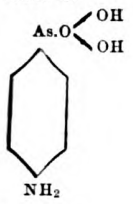


FIG. 2.

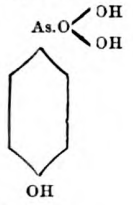

FIG. 3.

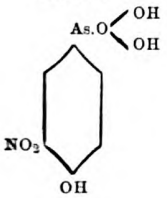

FIG. 4.

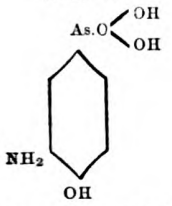

FIG. 5.

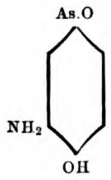

FIG. 6.

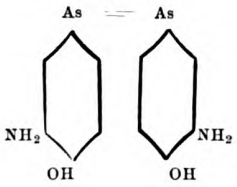

FIG. 7.

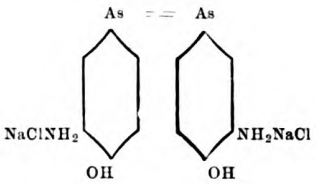

The amido radicle in Fig. 1 is replaced by a hydroxyl radicle by treatment with nitrous acid, which gives us para-oxyphenylarsenic acid (Fig. 2). By treating this new compound 2 with nitric acid, the nitro radicle is introduced into the meta position (Fig. 3). Reduction of compound 3 produces metaamidoparaoxyphenylarsenic acid (Fig. 4). Further reductions give us Fig. 5 and then Fig. 6—dioxydiamidoarsenobenzol, or "606." This compound being quite insoluble, a hydrochloride was prepared which is the yellow salt supplied by Professor Ehrlich. This on neutralisation with sodium hydrate gives us the sodium salt (Fig. 7). For commercial purposes "606" is prepared in a much simpler manner from arsenobenzol by the substitution of amido and hydroxyl radicles into the nucleus. It would appear that the activity of these substances depends upon the exact relationship of one radicle to another. Ehrlich considers that when there are two or more substitution molecules in the benzene ring one of which is capable (OH, or NH_2) of forming further combinations, the third radicle must be in the ortho position to the radicle capable of uniting with other compounds. In "606" the NH_2 radicle is in the ortho position to the OH radicle.

In the above compounds the amido radicle is perhaps of the greatest importance, for, as already stated, it was only after the discovery that in atoxyl the amido group was not bound up with the arsenic that these new and more efficient remedies were discovered. The fact that the arsenic is trivalent in "606" instead of being pentavalent as in the case of atoxyl is also believed to be an important factor in the efficacy of the remedy. Whether the amido radicle acts as the anchoring agent or as an auxiliary to the toxic influence of arsenic on the parasites is not quite clear, but it seems that the transposition of the amido radicle into the third position of the benzene nucleus has brought about a marked diminution in the organotropic properties of the medicament, without reducing in any way its parasitotropic qualities. In other words, these workers aimed at obtaining a remedy which approached as nearly as possible the most perfect therapy known—namely, serum therapy.

Chemotherapy has as yet been directed principally against micro-organisms of a protozoal origin, which the human body does not seem capable of destroying unaided. Recent researches have shown that Ehrlich's "*Therapia sterilisans magna*" is the most efficient method of dealing with such conditions. The introduction of this method of treatment was necessitated by his discovery that many organisms, chiefly of protozoal origin, had the power of becoming immune or resistant to injurious substances met with in the animal body. This fact explains the recurrence of trypanosomes and spirochætes in the blood of men and animals after apparent cures by a medicament. Relapses in infectious diseases can now be more intelligently explained by means of these facts.

The chronicity of protozoal and spirochæte infections is without doubt due to the same cause, as the parasites are able to protect themselves against each fresh output of antibody by the animal organism, till at last a condition of equilibrium is established between the two. In this state the chronic manifestations of the disease make their appearance. Nature for some reason does not seem able to upset this equilibrium until outside assistance has been given. In chemotherapy we have a means by which assistance can be given to the natural protective functions.

The manner in which a chemical compound such as dioxydiamidoarsenobenzol effects a destruction of the parasites in the organism is not a simple process. We know from the researches of Koch that the action is not of an antiseptic nature, as the ordinary antiseptics are as injurious to the host's tissues as to the parasites. A chemotherapeutic remedy must, therefore, possess a selective affinity for the parasite's protoplasm, in contra-distinction to that of the tissue cells. In order to explain this selective action Ehrlich has modified his side-chain theory of immunity to make it applicable to the study of chemotherapeutics. He terms the receptors in this case "chemoreceptors," the presence of such receptors in the protoplasm of the parasite being necessary before the remedy can fix itself thereto. When once the chemoreceptors of the parasite have been filled it is either so injured that it dies immediately or becomes an easy prey to the normal protective mechanism of the body. This hypothesis, then, of Ehrlich is really founded on the affinity of certain dye stuffs for certain tissues of the body. It is unlikely, however, that many chemotherapeutic remedies are sufficiently powerful to cause by themselves in every instance an immediate and complete sterilisation of the infected animal. Probably they destroy the majority of the parasites, and these destroyed parasites, being now in the condition of a soluble antigen, are the means by which a great increase of antibody is produced. The increased quantity of immune body may be sufficient to kill off any remaining parasites either by direct lysis or through phagocytosis. This probably occurs in the case of "606," as experiments on animals have shown that an elaboration of antibodies follows rapidly on the introduction of "606" into the infected organism, no matter at what stage of the disease the injection is made. In other cases the remedy has no direct lethal effect on the parasites, but nevertheless it injures them in such a way that certain of their vital functions are inhibited, as, for instance, reproduction, so that in a short time the parasites die out. It is also likely that some of these compounds so change the physico-chemical condition of the parasites' surroundings that the host's tissues and fluids are no longer suitable media for their continued existence.

Chemotherapeutic substances are usually grouped according to their manner of acting on the parasites as follows:—
1. No action on certain parasites either *in vivo* or *in vitro*. In such cases either suitable chemoreceptors are absent from the protoplasm of the parasite or the receptors of the tissue cells of the host's organs have a greater affinity for the remedy than have the micro-organisms. In the latter condition the organotropic properties of the medicament are in excess of its parasitotropic qualities. 2. No action *in vitro;* marked action *in vivo*. A result which may be brought about in one of three ways: (*a*) by the remedy undergoing some change, in the body of the animals, by which it is converted into a parasiticidal substance; (*b*) by causing an

inhibition of some vital function of the parasite such as reproduction; or (*c*) by stimulating the natural mechanism by which the host rids itself of micro-organisms in conjunction with either of the two previous effects. 3. Action *in vivo* and action *in vitro*.

As previously pointed out, the difficulty of treating protozoal infections is due to the power which the parasites possess of causing relapses, these relapses or recurrences being due to the facility with which these parasites become immune or resistant to various toxic bodies, whether of an inorganic or organic origin. Ehrlich attributes the resistance of these "fast" strains to a shedding of their chemoreceptors or to a diminution or complete loss of all avidity on the part of these receptors. Whatever this acquired resistance may be due to, the remarkable fact has been demonstrated that this property is persistent in the strain for generations afterwards. Thus we are able to realise the intention of Ehrlich's *therapia sterilisans magna*, since by destroying the parasites at one blow, so to speak, the possibility of a resistant strain springing into existence is prevented. In many of the cases where a *therapia sterilisans magna* is employed an artificial crisis is produced. This crisis apparently resembles in every way that which occurs naturally at a later period of the infection.

Precautions to be Followed Before the Exhibition of "606."

In order to diminish the occurrence of any injurious effects Ehrlich advises that before an injection of "606" be given a careful examination of the patient be made. Special attention should be paid to the condition of such important organs as the heart, liver, and kidneys. If changes are found which are likely to interfere considerably with the functional activity of these organs it is advisable not to give "606." In the same way gross alterations in the nervous system are contra-indications. If, however, these lesions are most likely of syphilitic origin the danger accruing from the use of "606" is greatly lessened, though the more recent observations have shown that the use of "606" in those cases where the nervous system has been considerably involved even by the syphilitic virus is fraught with considerable danger to the patient.

Ehrlich also considers that it is necessary to ascertain previous to the injection whether the patient has an increased susceptibility to arsenic or not. In order to ascertain whether this condition of "allergie" exists, a test similar in detail to von Pirquet's tuberculin reaction is made except that a solution of arsenic is used instead of tuberculin. If the patient has any hypersusceptibility to arsenic an inflammatory reaction is said to occur at the site of the puncture. Recent results have indicated, however, that such a precaution is wholly unnecessary.

Dosage.

In the earlier cases Ehrlich advised a dose of 0·3 gramme; this quantity, however, was found to be insufficient. The amount usually given now for an average adult is 0·6 gramme; more may be given without ill effects, but at present larger single doses appear to be unnecessary.

Technique of Injection.

In our earlier cases the remedy was given by intramuscular injection into the buttocks according to Alt's formula. More recently we have also used a neutral suspension of the remedy subcutaneously, as advised by Michaelis and Wechselmann. We have had no experience of intravenous injections and think there is no necessity for the employment of such means, though Schreiber and others have described improved effects. The least painful of these methods is, of course, the intravenous injection. The pain caused by the neutral suspension is slight in comparison with that following the injection of the remedy as advised by Alt, but patients of apparently equal fortitude appear to experience very varying discomfort.

The site of inoculation is also worthy of consideration; our observations tend to show that subcutaneous injections in the scapular region are rather less painful and inconvenient than intramuscular injections in the gluteal region. But the fact that in some cases there is apt to be a more severe local reaction after subcutaneous injections, or even the formation of a sterile abscess, rather tends to counterbalance the advantages of this method. Local irritation, however, appears to be considerably diminished if care is taken to prevent any of the injection remaining in the puncture or its neighbourhood.

Alt's method of giving dioxydiamidoarsenobenzol consists of injecting a solution of "606" in caustic soda. The preparation given out by Professor Ehrlich in sealed and exhausted glass bulbs is a hydrochloride of dioxydiamidoarsenobenzol, and this acid salt must be neutralised before use. On the addition of sodium hydrate a precipitate falls which consists of the sodium salt of this hydrochloride of "606." This precipitate is soluble only in excess of sodium hydrate. The pain which follows an injection of this alkaline solution is to some extent caused by the excess of alkali in it. Alt advises that the required quantity of the remedy should be placed in a sterile test-tube and dissolved in 0·5 to 1·0 c.c. of the purest methyl alcohol (*pro analysi*). To this solution 10 c.c. of sterile saline solution are added, and then the whole is neutralised with a normal solution of sodium hydrate; a few more drops of sodium hydrate are added till the precipitate which has been formed is all dissolved. 20 per cent. acetic acid is now slowly added to remove excessive alkalinity until the solution is slightly opaque, and after it has been made up to 20 c.c. it is ready for injection, on the addition of some anæsthetic such as eucaine. Owing to the readiness with which the compound decomposes it is essential that it be used immediately or shortly after it has been prepared. We, however, find it better to dissolve the required amount of "606" in much less liquid than is advised by Alt. If a little care be exercised in making up the remedy it will be found to go completely into solution in as small a volume of fluid as 6 or 10 c.c. By this means the whole amount of "606" can be given in one injection, thereby saving the patient a lot of unnecessary pain. The higher concentration of salts in the solution does not cause an increase of pain. The injection ought to be made high up in the gluteal region, in a spot situated about the junction of the upper and middle third of a line drawn from the anterior superior iliac spine backwards to the top of the gluteal fissure.

The neutral suspension of Michaelis must also be made up just previous to use. The "606" is dissolved in 0·5 or 1 c.c. of methyl alcohol as before, and then about 10 c.c. of sterile saline are added. This acid solution is made neutral to litmus or phenolphthalein by the addition of a solution of normal sodium hydrate. If the neutral point is exceeded a small amount of acetic acid may be added. The dioxydiamidoarsenobenzol is present as a bulky yellow precipitate. The mixture is then centrifuged for a short time, and the clear supernatant fluid poured off. The precipitate is now emulsified in 100 c.c. of saline and injected subcutaneously or intramuscularly. In the above manipulations the strictest asepsis must be observed as the preparation cannot be sterilised.

If it is wished to give an intravenous injection the remedy is made up according to Alt's method, but the volume of liquid should be made up to 200 c.c., so that a clear solution is obtained which is also much less alkaline.

All our injections have been made by means of a "record" syringe with an ordinary steel needle, which, however, should be heavily plated. The neutral suspension necessitates use of a needle with a wide bore.

The patients were all kept in bed for a few days after the injection in case of any complication arising and for better observation. Their sera were examined for the Wassermann reaction before the injection was given, and at intervals afterwards; where possible a search was also made for spirochætes before and after the injection.

In the following short abstract we have thought it necessary to present *all* the cases of syphilis treated by us, and we have been careful not to over-estimate the beneficial influence of the drug. With two exceptions, these patients have been admitted into the London Hospital by Dr. J. H. Sequeira, and have been continuously observed by him both while in his beds and afterwards in his dermatological clinic. The cases, therefore, have been controlled by a very wide clinical experience.

CASE 1.—A female, aged 23 years, had a large chancre in the middle of the upper lip in process of healing with ulceration of its inner aspect. There were a general desquamating papular rash, an ulcerated throat, and enlargement of glands. The sore had been present for about four months and the rash for one month. On July 19th, 1910, the patient was inoculated in both glutæi with 0·3 gramme of "606" in solution. Three days later the chancre had healed, the recent spots had disappeared, while the older ones were fainter. After six days all spots had gone, leaving a pigmentation only. On the eighth day no glands were palpable, and on the tenth slight pigmentation of the rash only was observed. After three months the patient was in perfect health and had increased in weight 8 lb. No general reaction was

observed in this case. The local pain did not appear to us to be severe. On Oct. 20th the Wassermann reaction became slightly positive. On Nov. 3rd the patient returned with slight malaise, some four or five spots, two mucous patches, and slight sore throat. No spirochætes were found in the lesions. Wassermann reaction positive. On Nov. 15th she was given 0·6 gramme of "606" in solution intragluteally, which produced a rapid disappearance of the symptoms.

CASE 2.—A male, aged 30 years, had a hard chancre 1½ inches long on the lower lip. The right submental and cervical glands were enlarged, but there was no other sign of syphilis. The patient was said to have been bitten on the lip in a fight. The sore had been present for three weeks. On August 16th, 1910, he was inoculated in both glutæi with 0·3 gramme of "606" in solution, and in two days the chancre was softer and the glands were smaller. Six days after the injection the glands were still enlarged, but the chancre was healing and much smaller. On the ninth day the unhealed area was three-quarters of an inch long. In five weeks the patient returned with the chancre no smaller and a very marked macular rash on the forearms. He was, therefore, again inoculated on Sept. 22nd with 0·6 gramme of "606." The chancre rapidly healed, leaving a slight induration; the rash faded. Two and a half months after the first inoculation he showed no signs of the disease. After the first inoculation the pain was very severe in both glutæi and in the knees and the calves, and it lasted for two days. There was, however, no general reaction; the second inoculation was comparatively painless. In this case the temperature rose to 99·2° F.

CASE 3.—The patient, aged 29 years, a male, was melancholic. He had a bad septic throat and suffered from earache. He had also a macular rash which was fading from the trunk and was marked on the buttocks. He had had a sore on the penis in October, 1909, without any rash. This latter did not appear until June, 1910, at which time also the sore throat and earache started. On August 13th his Wassermann reaction was completely positive, but on the 26th it was only partially so. At this latter date he was injected with 0·4 gramme of "606" in solution into both buttocks. On the next day the earache had gone. After three days his throat was quite clean and injected only, while after five days there was no longer any rash. However, after seven weeks, the throat was no better and the earache started on the other side. At the same time his Wassermann reaction again became completely positive and further treatment is intended. The pain at the time of inoculation was moderate only. There was no general disturbance.

CASE 4.—The patient, a female aged 19 years, had a small chancre in the middle of the upper lip and enlargement of glands. The chancre had been present for 10 weeks. On Sept. 9th, 1910, she was inoculated with 0·4 gramme of "606" in solution into both glutæi. In seven days the chancre was almost healed, and in 19 days it was completely healed. She has not been observed again. The pain was moderate and lasted for 24 hours. The highest temperature was 99·2° F., and the quickest pulse-rate 95.

CASE 5.—A male, aged 34 years. This man had a large suppurating sore on the left cheek with very marked general rash and glandular enlargement. He had been bitten on the cheek. The sore had been present for five weeks and the rash for 17 days. On Sept. 22nd, 1910, he was inoculated with 0·6 gramme of "606" in solution into both glutæi. In seven days the rash had nearly gone and there was very little discharge from the sore. After two weeks the sore was quite healed; the former rash was marked by a pigmentation only and the glands were still enlarged. He had gained 8 lb. in weight. After five weeks there were no signs of the disease. Following inoculation the pain in the small of the back was very severe for five days. For three days the temperature varied between 97° and 100° F., and during the same time the pulse ranged from 90 to 96. There was no other reaction.

CASE 6.—A female, aged 26 years, had a general macular rash. Her face was very badly affected and was desquamating. There was general enlargement of the glands. This rash had been present for six weeks. She was inoculated in the glutæi on Sept. 29th, 1910, with 0·5 gramme of "606" in solution. On the day after there was a marked Herxheimer reaction followed by a rapid diminution of the redness. After seven days there was little but pigmentation. On the fourteenth day there was still a slight mottling and the glands were enlarged. Five weeks after the inoculation the patient was quite well. The pain did not appear to be severe and there was no general reaction.

CASE 7.—A female, aged 26 years, with marked general papular and macular eruption. The throat was sore and the glands were enlarged. The rash had been present for about 10 days. She was inoculated on Sept. 29th, 1910, in both glutæi with 0·5 gramme of "606" in solution. In one day the former very marked rash on the hands and face was only visible on close inspection. The rash faded until on the seventh day there was little left; the sore-throat also had gone. After four weeks there was still a slight pigmentation in places. This patient did not complain of much pain and there was no general reaction.

CASE 8.—The patient was a male aged 26 years. He had a small penile chancre with no secondary symptoms. The chancre had been noticed for about three weeks. He was inoculated on Oct. 6th, 1910, in both scapular regions with 0·6 gramme of "606" in suspension. In one day the chancre was flatter and cleaner. On the fourth day it was clearly healing and on the fifteenth day had completely healed. No secondary symptoms have appeared. The local pain was mild. On the night of the inoculation the patient had a profuse sweat with a temperature of 101·4° F., a pulse rate of 100, and a respiration rate of 24. The urine was normal. After the first day there was no further disturbance.

CASE 9.—The patient, a male, had a widespread indurated ulceration of the whole lower lip, the chin, the left cheek, and half of the upper lip. This condition had lasted for nine months. For the past five years similar conditions had arisen on various parts of the body and usually had taken four months to heal with iodide of potassium. There was an indefinite history of syphilis and the Wassermann reaction was negative. The patient was inoculated on Oct. 6th, 1910, with 0·6 gramme of "606" in suspension in both scapular regions. In four days the ulceration was very much cleaner, but the inflammatory area was no smaller. In two weeks the area was much smaller and there was active epithelial proliferation. After three weeks the healing was still progressing and in one month was nearly complete. A considerable redness, however, still remains. Very little pain followed the inoculation. In this case also there was a profuse sweat during the first night with a temperature of 99·4° F. Otherwise there was no general disturbance.

CASE 10.—The patient, a male, aged 40 years, was under the care of Dr. Arthur Whitfield at King's College Hospital. He had a large scaling and infiltrating patch over the left forehead and including the left eyelid and a great part of the nose. There was a tendency to ulceration at one place only. The man had been infected 23 years before and had had a gummatous relapse 10 years ago. Dr. Whitfield first saw him in May, 1909, when he had a widespread condition of the left upper arm which had been diagnosed as psoriasis. This cleared up rapidly under mercurial inunctions and later pills. He discontinued treatment with the present result which has dated from the summer of this year. On Oct. 10th, 1910, he was inoculated with 0·6 gramme of "606" in suspension in both scapular regions. In 24 hours the lesion was paler and in four days it was almost flat though heavily pigmented. In ten days a large pustule occurred on the nose with an increase of redness. This healed in about four days. In three weeks the lesion was quite resolved, leaving some brown staining only. He increased 5 pounds in weight in the first week. The pain after inoculation was severe and there was a rise of temperature to 100° F.

CASE 11.—The patient, a male, aged 15 years, had congenital syphilis and a widespread inflammatory and ulcerative condition of the face, nose, and upper lip which had provisionally been diagnosed as lupus. The nose was depressed and obstructed by discharge. Double otitis media with affection of the internal ear was present, as well as otorrhœa. The hearing was very feeble on the right side and was absent on the left. There were interstitial keratitis and choroiditis on both sides. The patient was blind in the left eye, and on the right side there were very high myopia and dimness of vision. The condition had been progressing for four years. On Oct. 10th, 1910, he was inoculated with 0·1 gramme of "606" in suspension in the scapular region, and on the 12th with 0·2 gramme into the buttock. On this day (two days after the first inoculation) he spontaneously remarked that he could see better. On the third day the injection of the left eye and the opacity of the pupil were less. In five days there was very marked diminution in the size of the swollen lip. The inflammatory redness had gone from the face. The nasal discharge had ceased, permitting a cessation of the dressings. On the seventh day the patient could breathe freely through his nose. Ten days after the first inoculation he had a bad "cold," with foul aural discharge and increased redness of the lip. On the 25th he was again inoculated with 0·2 gramme of "606" in the shoulder and since then there has been a slow but persistent improvement in his condition. Both inoculations in the shoulders produced large red indurations but little pain. After the second inoculation the temperature rose to 99·4° F. and the pulse to 100; after the third the temperature was 100°.

CASE 12.—The patient, a male, aged 22 years, was under the care of Dr. J. Sangster Greig at West Ham Union Infirmary. He had a phagedenic chancre on the side of the prepuce 1½ inches long, associated with ulceration of the glans penis. There was a general papular rash, glandular enlargement, and sore-throat. The chancre had been present for two months and the rash one month. On Oct. 10th, 1910, he was inoculated with 0·6 gramme of "606" in solution into both glutæi. A slight Herxheimer reaction followed. In six days the rash was gone, the chancre half healed, and the glands practically normal. In 13 days a small area of the glans only was unhealed. In three weeks he was quite cured, and had increased 10 pounds in weight. The local pain was not severe, and the temperature rose to 99·6° F. only.

CASE 13.—The patient, a male, aged 25 years, had a healed chancre and a fading secondary rash all over, with much desquamation. The rash was marked on the face, neck, bend of elbows, &c. There were general glandular enlargement and gleet. The chancre appeared three or four months before and the rash six or eight weeks. On Oct. 12th, 1910, he was inoculated with 0·6 gramme of "606" in suspension into both shoulders. In three days the rash had nearly gone from the trunk and was fading from the face; in seven days the rash was hardly visible, while in 16 days all signs of disease had disappeared. He had very little pain and a temperature of 99·5° F.

CASE 14.—The patient, aged 28 years, was the mother of Case 15. There were no symptoms of syphilis. The Wassermann reaction was negative. Her children are healthy, the last being born four and a half years ago. There was a history of syphilis, she having had a rash which started two years ago and lasted until the time of conception of Case 15. She was inoculated on Oct. 14th, 1910, with 0·5 gramme of "606" in suspension in both shoulders. There was only slight pain. Just after inoculation she developed a severe "cold," with a temperature of 101·6° F. and malaise. This lasted three days.

CASE 15.—The patient was a male aged 4 weeks. He had pemphigus and a rash all over the body and nasal discharge. He had had six inunctions of mercury with benefit, but other spots were coming out. Dr. Sequeira thought that the child might live. The condition started four days after birth. The baby was not inoculated but was suckled by the mother. Three days after the mother's treatment the rash and pemphigus had nearly gone. In ten days the baby was quite well and is now thriving. No ill-effects were observed in the baby.

CASE 16.—The patient was a male aged 2 weeks. There were severe general bullous pemphigus and diarrhœa. The child had shed nearly all his skin. Dr. Sequeira thought that the baby would die. On Oct. 14th, 1910, he was inoculated with 0·02 gramme of "606" in suspension into the glutæus muscle. In three days the rash and pemphigus had practically gone. In four days there were a few spots only and no diarrhœa. Up to the seventeenth day the baby had been thriving; on this day he was again inoculated with 0·06 gramme of "606" in the shoulder. Local redness and swelling followed the first inoculation and seven days after a very small slough separated from the point of inoculation. There was no general disturbance. The second inoculation also has been followed by no ill-effects.

Disappearance of spirochætes.—The action of "606" on the Spirochæta pallida in the primary lesion is very rapid, as in Cases 2 and 8. No spirochætæ could be found in the primary lesion 24 hours after the remedy had been given, though just previous to the injection they were present in large numbers. The greatest destruction of spirochætes apparently took place 5 to 12 hours after the injection. No doubt those actually in the system are attacked at an earlier period.

Mercury, on the other hand, takes about three weeks to bring about this result. The above fact alone serves to stamp dioxydiamidoarsenobenzol as the greatest anti-syphilitic remedy we possess.

Leucocytosis.—In none of the above cases have we observed any such marked degree of leucocytosis as has been described by different writers.

Effect of "606" on the Wassermann Reaction.

Number of case and stage of disease.	Dose.	Before.	Weeks after—

C=Completely positive reaction. M=Medium positive reaction.
S=Slightly positive reaction. O=Negative reaction.

We do not suppose that "606" can directly influence the Wassermann reaction, but by its destruction of the spirochætæ it removes the cause. At any rate, the rapidity with which in some cases the patient's serum loses the power of giving a positive Wassermann reaction is one of the greatest arguments in favour of Ehrlich's new specific. In our own cases, as can be seen in the above table, the earliest period at which the reaction has disappeared after an injection is three weeks (Cases 1, 2, and 8). It will be seen that two of these cases were in the first stage of the disease. The reaction disappears much more slowly in cases of secondary syphilis, and, in fact, has already persisted in some of our cases for seven weeks. These results are not surprising, as in primary syphilis the Wassermann reaction is usually a weak one, though completely positive. There is in these cases little or no excess of reacting substances in the serum. In secondary syphilis, however, there is a much larger quantity of the Wassermann-producing substances in the serum, and it is only logical to expect that they will take a longer time to disappear. We are convinced that the information supplied by the Wassermann test is an essential indicator of the patient's progress. If the reaction fails to become negative after an interval of several weeks, it is to be suspected that the patient is not doing so well as he should, and in all probability will have a relapse, as was the case with patient No. 3.

Effects on Lesions.

In the case of primary lesions, genital or extragenital, the process of repair is very rapid. In contradistinction to the five or six weeks required for the disappearance of a chancre under ordinary treatment, only from 10 to 14 days were required for complete healing. Secondary lesions, as a rule, show an improvement within 24 hours of an injection of "606." In the case of the secondary eruption, however, the pigment appears to persist for a long time; this persistence of the pigment is no doubt only relative, as after an injection of "606" the absorption of the inflammatory lesion is no longer a gradual process as when mercury is used, but an immediate one. In tertiary lesions the effects are much more varied. Some disappear as if under a magic influence; others, again, show little or no alteration for some days after the injection. In congenital syphilis even of the worst types the rashes disappear in two or three days. Lesions of a more chronic nature, such as interstitial keratitis, resolve very much more slowly.

Question of Temperature Response to "606."

The alteration in temperature after an injection of "606" in cases of primary and secondary syphilis is comparable to what occurs in certain acute infections which terminate by crisis. In other words "606," owing to the rapidity with which it sterilises the human organism of spirochætes, produces a cure in these stages by a definite crisis. The patient's temperature rises as a rule one or two degrees (100° or 101° F.) within 12 hours, after which it falls almost as suddenly as it rose. The patient at the same time experiences a profuse sweat. If the temperature is high at the time of inoculation it usually falls to normal about 24 hours later. This temperature response is not observed in the majority of patients suffering from latent or tertiary syphilis. No doubt the flooding of the system with an excess of soluble spirochæte products is the actual cause of these phenomena.

Relapses.

In Cases 2 and 3[1] it will be noticed that relapses occurred, but not relapses in the sense of a clinical recurrence after a clinical cure. Neither of these patients had cleared up after one inoculation, which, it must be observed, was in each instance small. These accidents, to a large extent, must depend upon the *size* and *spacing* of the doses. The question arises as to whether one dose on the average is sufficient to produce complete sterilisation of the body, however large it may be. We take it that "606" is intended to have a lethal influence on spirochætes, but that all the spirochætes in the body are not destroyed by this influence. The residuum, great or small, is overcome by the antibodies to "endotoxins" liberated from those spirochætes destroyed by the "606." Thus if there are few spirochætes in the body, there will be a small output of antibody, perhaps insufficient to finish the cure or at least liable to delay it. Such a state may be present when the Wassermann reaction is negative or feeble. This is held to imply the presence of a small quantity of the virus in the body. It is also known that arsenic circulates in the system for a very short time after injection: it is very rapidly "fixed" by the tissues, especially the kidney. What, then, is to be expected in cases such as Nos. 3 and 9 with feeble and negative Wassermann reactions? The arsenic which is absorbed destroys, indeed, some spirochætes, but most is "fixed" by the tissues and lost. The production of "endotoxin" and subsequent antibody is small. Sterilisation in the one case was incomplete; in the other recovery was at least slow, and will probably also be incomplete. In cases of this sort, therefore, as also in cases of primary syphilis, if not in syphilis of any variety, we think that more than one dose will be found to be more certain in action. Ehrlich recommends an initial large dose given intravenously, or if there is thought to be objection to this, intramuscularly, in solution. This ensures a rapid absorption and a sharp *ictus immunisatorius*, leading to a maximum destruction of spirochætes and production of antibody. Then, since the first injection will be rapidly wasted, on the second or third day, a second dose in suspension should be given to act as a "depôt" over a considerable time. All our recent cases have been treated on this principle. The patient is first given an injection of 0·5 to 0·6 gramme "606" in alkaline solution intramuscularly in the gluteal region, the volume of liquid injected not being more than 10 c.c. Three days later he is given 0·4 gramme "606" neutral suspension intramuscularly in the opposite side.

The employment of "606" will probably assist in the elucidation of several points of interest in the immunity to syphilis. Among these are the changes which occur in the serum components of patients who have been treated with "606." That the Wassermann reaction should rapidly become

[1] Since this paper went to press Case 1 (*q.v.*) also relapsed, after an apparent cure lasting nearly four months.

negative is not to be wondered at in view of the potency of the drug. We provisionally consider this reaction to be due to the presence of abnormal compounds in the blood, such compounds being the direct result of a destructive action by the living syphilitic virus on the tissues. If the virus is destroyed these compounds will no longer be formed, and those already present will be excreted in a few weeks or less according to the quantity originally present. The antibody which is formed by the presence of "endotoxins" is presumably a specific antibody and quite distinct from the Wassermann body, which is thought to be a direct degeneration product. If the latter were an antibody it could not be diminished by specific treatment. This has been demonstrated in experimental trypanosomiasis, where both specific antibody to the trypanosome and the Wassermann body are capable of being separately demonstrated.

Some writers have stated that a negative Wassermann reaction may become positive after inoculation. They assume that the soluble products, "endotoxins" of the spirochætes, are capable of bringing about that tissue degeneration which results in the Wassermann reaction. In the case of a negative reaction such products would be too few to detect, but as a result of inoculation a maximum output of "endotoxin" from the destroyed organisms suffices to produce the necessary tissue degeneration and a positive reaction. In three of our cases in which the reaction was negative or slight before inoculation no increase was observed. Any change has always been in the opposite direction. Many recent writers, moreover, have also failed to observe any such change, and as we are at present of opinion that in acute syphilis the Wassermann reaction is due to the active intervention of living spirochætes we are not surprised that these occurrences are rare.

In the literature there are already on record a few cases where the injection of "606" into the mother of a congenitally syphilitic baby resulted in a rapid and complete cure of that baby through the agency of the mother's milk. Such cases are explicable in two ways: first, that the injection of the mother with a positive Wassermann reaction by destroying a number of spirochætes produces in her a large amount of antibody, and that this antibody secreted in the milk brings about the recovery of the child; and secondly, that there is a direct transference of "606" by the milk. Ehrlich favours the former view, since in the cases published it was stated that no arsenic was found in the milk, or in a quantity insufficient to explain the therapeutic result. If this be the case it is difficult to explain our case No. 14. This woman had a negative reaction but a recent history of syphilis. In these circumstances she could not have produced sufficient antibodies as the result of a destruction of spirochætes. It is therefore possible that the "606," merely by stimulation of the cells which previously had produced syphilitic antibody, caused a sufficient amount of these bodies to appear in the milk. It is, however, also possible that on the application of more refined methods arsenic may be demonstrable in the milk in larger quantities, and may take a more direct part in the cure than has been supposed.

This stimulating property of "606" may account for the great rapidity with which these antibodies are elaborated. The onset appears to be very much sooner than is the case in other immunising processes and cannot be altogether due to the large amount of antigen in the circulation as a result of the inoculation. That "606" has a stimulating effect on many metabolic processes can hardly be doubted. The subjective sensations of the patients are greatly improved, and where weight has been lost it is rapidly regained; for instance, Case 2 gained 7 pounds in 10 days, while Case 12 gained 10 pounds in 18 days. Further, inflammatory conditions subside, and a case of myelogenous leukæmia with 240,000 white cells per c.mm. before inoculation by us, one week afterwards had only 120,000. Such conditions as dropsy, œdema, and jaundice in one moribund non-syphilitic individual disappeared after inoculation, even though the causative malignant disease killed the patient in a few days.

Certain phenomena noticed from time to time while using "606" in syphilitic cases can only be explained on the assumption of endotoxins liberated from the spirochætæ. It has been shown that very young congenitally syphilitic infants are unsuitable for treatment except with very small doses, and the fatal results are explained by the very large quantity of endotoxins which must be produced from the innumerable spirochætes present in such cases. Again, we have observed the Herxheimer reaction in two cases. This reaction appears to be considered to be due to an *insufficient* dosage. It is suggested that the spirochætes are not sufficiently rapidly destroyed, that they have time to react to the noxious influence of "606" with an increased production of poisons. In our cases, however, the dose was not particularly small. We are at present inclined to look upon this phenomenon as being of the nature of an anaphylactic manifestation in an individual particularly sensitive to the syphilitic "endotoxins": a phenomenon comparable to those following the introduction of tuberculin or any other antigen into an already sensitised subject. These reactions have been particularly mentioned by Ehrlich as a cause of dangerous symptoms or death in the case of general paralysis and similar conditions. If in such a case of nervous degeneration a reaction occurs in an essential nerve, such as the vagus, the *exitus lethalis* will probably follow, and such an event, if these cases be operated upon, must be guarded against by the exhibition of *very small* doses.

The importance of "606" as a destroyer of spirochætes cannot be over-estimated, even apart from the beneficial effect upon the patient. In those cases in which spirochætes were demonstrable in very large numbers before inoculation, none were found in less than 24 hours, even after prolonged search. This fact has already been fully established. The importance of the observation lies in the probability that cases of syphilis can be rendered practically non-infective in a day or two. If this be true, Ehrlich will have swept away the scourge of 2000 years and given into the hands of any State, which will avail itself of it, a weapon for the forcible suppression of syphilis.

NEW CHEMICAL LABORATORIES AT UNIVERSITY COLLEGE, LONDON.—On two previous occasions we have called attention to an appeal for £70,000 for the purpose of providing University College, London, with new chemical laboratories. We have now received a letter from Prince Arthur of Connaught, President of the appeal committee, stating that it is a matter of particular urgency that the sum of £25,000 should be raised before Christmas Day in order that the Senate of the University may exercise the option to purchase the Gower-place site. Towards this sum over £10,000 have now been raised. Donations sent to His Royal Highness, addressed to University College, London, will be acknowledged by him.

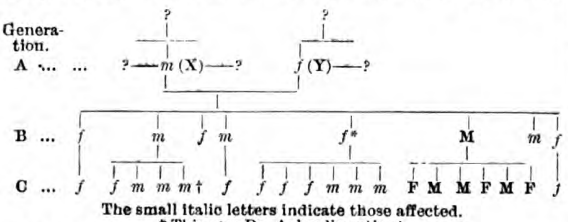
FOOD CONGRESS.—The Deuxième Congrès de l'Alimentation will take place in Liége from Oct. 1st to 4th, 1911. This Congress has been organised in order to continue the work, as far as Belgium is concerned, of the Congress which was held at Paris in 1909 organised by the Société de la Croix Blanche de Genève and the Food and Hygiene Congress which was recently held at Brussels, organised by the Belgian Government. Foreign specialists are invited to take part—viz., physiologists, chemists, bacteriologists, hygienists, jurists, producers, merchants, &c., in order that they may examine the whole question of food and discuss the measures to be taken to reconcile the requirements of hygiene and public health with commercial interests. The labours of the Congress will chiefly relate to the following food products—viz., milk, cheese, meats, poultry, fish, eggs, pickles, fats, bakery products, pastry, confectionery, chocolate, preserved vegetables, fruits, mushrooms, sugars, syrups, glucose, jams, tinned provisions, spices and condiments, waters, lemonades, ice, beers, wines, ciders, alcoholic drinks, vinegars, liqueurs, fruit juices, syrups, &c. The president of the congress is Professor M. A. Jorissen, of the University of Liége, and an official of the Permanent Belgian Commission of Human Alimentation. The vice-presidents are: M. Julien Delaite, M. de Molinari, M. J. Raymond, M. L. Rutten, M. E. Sohier-Beaujean, and M. J. Van Zuylen. The secretary-general is Dr. F. Schoofs, secretary-general of the Permanent Belgian Commission of Human Alimentation. The treasurer is M. E. Halleux, barrister and secretary of the Union of Purveyors. All communications should be addressed to the secretary at Rue des Guillemins, 27, Liége, Belgium. The subscription is fixed at 10 francs. The title of "*Membres donateurs*" will be given to those who subscribe at least 50 francs, and the title of "*Membres protecteurs*" to those who subscribe at least 200 francs. The family of regular members may become *membres associés* at 5 francs per person and will be invited to the fêtes.

A PEDIGREE SHOWING BI-PARENTAL INHERITANCE OF WEBBED TOES.

BY H. P. NEWSHOLME, M.B. OXON., M.R.C.P. LOND., B.SC. LOND.

IT is of rare occurrence to find a family in which the same abnormality has been inherited from both parents. Dr. E. Stainer, in a very interesting paper,[1] has collected from the literature six pedigrees of this nature, among which is included the one shortly to be discussed. These appear to be the only instances recorded.

The family now in question was brought under notice through a patient admitted to St. Thomas's Hospital in June, 1910, under Dr. T. Dyke Acland, who has very kindly allowed me to publish the facts. The patient, a woman aged 45 years, was admitted to hospital on account of visceroptosis, severe Dietl's crises, and glycosuria. It was discovered accidentally, during a routine examination, that the second and third toes of each foot were webbed as far as their terminal phalanges. Further inquiry showed that this deformity occurred through three generations and involved 22 members of a family of 29, as indicated in the accompanying pedigree. Other members of Generation A, as well as



The small italic letters indicate those affected.
* This was Dr. Acland's patient.
† This individual had webbing of the third and fourth fingers of the right hand, but no webbing of the toes.

one or other parent of both X and Y, were probably affected, but no precise information on these points could be obtained. All the marriages occurring in generation B were with normal persons.

Owing to the rarity of such pedigrees, it seems important to mention the sources of information and the evidence of its reliability. 1. Nearly all the facts were given by the patient herself (No. 5, Generation B). The patient was a quiet, inexcitable, sensible woman, not at all inclined to exaggerate or to romance. She showed no sign of hysteria or of a morbid desire for sympathy or attention. She had, moreover, no motive for endowing other members of the family with a deformity of which she herself was oddly ashamed. 2. These facts were corroborated, and others added, by a brother (No. 6, Generation B); also by a sister (No. 3, Generation B), who is attending the out-patient department of St. Thomas's Hospital for diabetes. The brother (No. 6) is quite positive that he and his children are the only members of this branch of the family free from webbing. 3. The presence of webbing was verified in the patient and in one of her children, the only members of the family who could conveniently be examined. 4. The informants mentioned above believe, but cannot be quite certain, that the webbing has nearly always involved the second and third toes of each foot. A notable exception will be seen in a note to the pedigree. 5. The fact that *both* parents (X and Y) had similar webbing has been impressed on the family by a dramatic incident, the memory of which is now evidently a precious family possession. The presence of webbing in both parents was not recognised till the birth of their first child, when each parent claimed its webbed toes as his or her particular contribution. Naturally an unveiling of parental toes followed, and resulted in mutual surprise, mutual satisfaction, and the amusement of younger generations. 6. Both X and Y are said to have had several brothers and sisters with webbed toes, and are believed themselves to have inherited the deformity from their parents. This information was so lacking in precision that I have been unable to include these members in the table. From X and Y onwards, however, the facts are clear and complete.

The only question to be considered here concerns the extent to which this pedigree conforms with Mendelian principles. Mendelism aims at attacking problems of heredity by dissecting the individual's almost innumerable traits into as many pairs of opposed characters as it can. To choose instances at random, it might take pairs such as the following: long hair, short hair; fair hair, dark hair; tallness, shortness, &c.; and by working out the transmission of each pair get finally, more or less completely, the inheritance of the individual. Since physical are far more easily measured than mental characters, Mendelism necessarily limits itself almost entirely to the former. In the case in question, "webbing" and "no webbing" must be the two opposed factors. The character "webbing" is, of course, the one which renders this family peculiar, while the character "no webbing" it shares with the rest of mankind.

Of the two gametes, spermatozoon and ovum, which unite to develop into any of the individuals in this family, both may contain or both may be free from the subtle property which gives rise to webbing, so that the individual into whom they develop is either saturated with or quite free from the conditions which give rise to webbing. But there is another alternative: one gamete may carry the factor "webbing," while the other may not. (The second may conveniently, though not accurately, be described as carrying the factor "no webbing," which is, strictly speaking, not a factor but the absence of a factor.) In such a case the individual resulting from their union will, so far as this character is concerned, be a hybrid or *heterozygote*. The germ-cells which he or she bears will not all be exactly the same in properties. All will be spermatozoa or all will be ova, but they will bear the impress of the gametes from which they are descended in that some will contain the factor "webbing" and others the factor "no webbing." Moreover, those gametes carrying one factor will equal in number those carrying the other factor. The whole structure of Mendelism stands on this one principle, that the germ-cells of a heterozygote can be divided into two equal groups, those in one group containing one factor and those in the other its opposite.

Further, given an individual resulting from the fusion of two gametes, one carrying the factor "webbing," the other the factor "no webbing," he will be webbed or not webbed according as webbing is or is not stronger than, or *dominant* to, absence of webbing. The weaker factor here becomes latent or *recessive*.

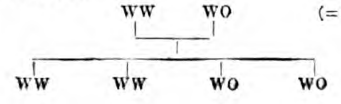
In considering each individual it will be convenient to have signs for the two classes of gametes. Thus that group of gametes which contains the character "webbing" may be represented by W, and the group containing the character "no webbing" by O. A heterozygote, then, will be indicated by WO; and, according as we find on trial "webbing" or "no webbing" to be a dominant factor, so a pure dominant and a pure recessive will be represented by WW and OO, or *vice versâ*.

Now dealing with the family more particularly the following possibilities arise with regard to X and Y:—

1. *Webbing may be a recessive character*, so that it will lie latent unless both individuals are pure recessives, developed from gametes containing only the character "webbing" and themselves bearing gametes containing only the same factor. Since X and Y are known to have been webbed they must on the above hypothesis have been pure recessives. In that case, since neither contains the group of gametes O the children resulting from their intermarriage would necessarily all be pure recessives, and would hence all be webbed. But generation B contains one unwebbed member. Webbing cannot then be recessive. We must therefore conclude that *webbing is a dominant character*.

2. *Both X and Y may be pure dominants.* Then, as neither parent would bear the recessive group of gametes O none of their children could be free from webbing. But, as has been seen, one member of generation B is not webbed. The assumption, therefore, that both parents are pure dominants must be wrong.

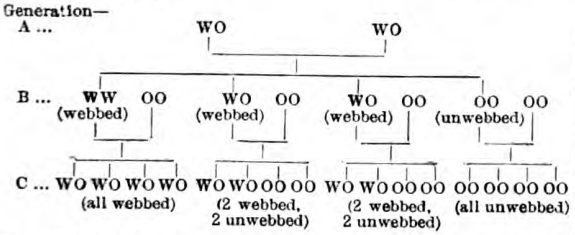
3. *Of X and Y, one may be a pure dominant, while the other is a heterozygote.* The Mendelian chart of their progeny would be as follows:—



[1] The Hereditary Transmission of Defects in Man (Oxford University Press).

Since webbing is dominant all the offspring would be webbed, although only half of them are pure dominants. Since one member of generation B is unwebbed, the hypothesis that of X and Y one is pure dominant and the other a heterozygote must be wrong.

It must be concluded, then, that (*a*) *webbing is dominant, and* (*b*) *both X and Y are heterozygotes*, each derived from gametes of opposite qualities as regards webbing, and each bearing both groups of gametes W and O, and bearing them in equal numbers, each, therefore, being represented by the sign WO. On Mendelian principles the offspring of the marriage of two heterozygotes would be as follows, the children of the first marriage marrying in their turn, but marrying normal individuals, OO:—



For convenience of reference these have been lettered in Generations A, B, C, to facilitate comparison with the pedigree under consideration. The results of comparison may be tabulated as follows:—

	Mendelian result.	Actual pedigree.
Generation B	1 unwebbed in 4	1 unwebbed in 8
Generation C	8 „ „ 16	6 „ „ 19

As they stand, the variance between the two sets of figures is so great as to suggest that the observed facts run counter to the Mendelian theory. But the error inherent in small numbers must always be borne in mind. The accident of one child more or less in each generation would have affected the proportions very materially.

The extent of this error can be estimated by means of Poisson's formula, in which the limits of error per unit are $\pm 2\frac{\sqrt{2mn}}{\mu^3}$, where μ = total number of cases recorded and m = number in one group and n = number in the other group. Here for generation B, $\mu = 8$, $m = 7$, $n = 1$; while for generation C, $\mu = 19$, $m = 13$, $n = 6$. Substitution of these values gives the following results:—

Generation B. Limits of error for unity = approx. $\pm 0{\cdot}33$.
„ „ 8 cases = $\pm 2{\cdot}6$.

Thus, allowing for this possible error of 2·6 in 8, dependent on the small data available, the pedigree might conceivably have shown, instead of 1 unwebbed in 8, any proportion between 3·6 in 8 and 0 in 8. The Mendelian ratio of 1 in 4 (2 in 8) obviously lies within these extremes.

Generation C. Limits of error for unity = approx. $\pm 0{\cdot}33$.
„ „ 19 cases = $\pm 6{\cdot}3$.

Here, where the actual ratio was 6 unwebbed in 19, the extreme limits of variability are from 12·3 in 19 to 0 in 19. The Mendelian value of 8 unwebbed in 16 (9 in 19) lies within these extremes. In both cases, therefore, the Mendelian value is seen to be not incompatible with the actual data obtained.

These considerations show only that the pedigree in question neither supports nor throws doubt on the Mendelian hypothesis. It is like all similar small pedigrees, quite neutral in the argument which it provides. This must necessarily be the weak point in all family pedigrees where the members can be numbered only in tens instead of in hundreds. Obviously deductions must be made very cautiously, if at all, where the possible error in either direction reaches, as in this instance, 30 per cent. of the number of cases observed. For the same reason it is dangerous to conclude, on the grounds that one large fraternity in Generation C is seen to be webbed throughout and another to be quite free from webbing, that therefore the one indicates a pure dominant, the other a pure recessive strain.

This family is interesting also in connexion with a defect in sugar metabolism, which occurred in three members of the family (Nos. 2, 3, and 5, Generation B). The patient herself has mild glycosuria; an elder brother died from diabetes and pulmonary tuberculosis, and one sister is being treated in the out-patient department of St. Thomas's Hospital for diabetes. No further facts bearing on this point could be obtained with regard to other members of the family.

NOTE ON AN OBSCURE CASE OF PERITONITIS.

BY R. H. NORMAN, M.D. LOND.

THE following case seems worth reporting.

A male, aged 33 years, was seen by me on Nov. 12th last. He complained of severe continuous pain in the epigastrium, both hypochondria, and the right iliac region. There was no point of special tenderness. He had vomited several times that day, the vomit being gastric only. The abdomen was distended and moved with respiration. Nothing abnormal could be felt. The temperature was 102° F. The bowels were constipated. On the next day he was in much the same condition, the pain being a little less after some small doses of opium. The temperature at 9 P.M. was 104°. The bowels had been opened by enema, and subsequently two loose, bright yellow motions were passed. The colour of the motions suggested enteric fever, but no other symptom pointed to that diagnosis. He had been ailing a week or ten days, feeling languid and having a poor appetite, but he kept at his business until the morning of the 12th. I took a specimen of his blood and sent it to the Jenner Institute, and a positive Widal reaction was reported. On the 14th the temperature at 10 A.M. was 102°, and at 9.30 P.M. 104°. The abdominal pain was still severe, especially in the epigastrium and the left hypochondrium. On the morning of Nov. 15th I found him much worse, with a running, rapid pulse of 120–130, and temperature 102°. The abdomen was much distended, with little or no movement in respiration, general tenderness, but no rigidity. I suspected perforative peritonitis, but could not satisfy myself that this was so, the liver dulness being normal. He was carefully removed to the North-Eastern Hospital. The grave abdominal condition pointed to the immediate need of a cœliotomy as the only chance of saving him. This was done, but the patient never rallied.

A post-mortem examination was made, and Dr. Frederic H. Thomson has very kindly supplied me with the following notes: "A mass of inflamed tissue was found behind the stomach in which were several broken-down caseous glands. There was a cavity in this mass, and from it one sinus led into the stomach. The ulcer in the stomach was not a recent one. Another sinus led to a caseous mesenteric gland, and two others led into the peritoneum. The openings into the peritoneum were apparently recent. There were a number of caseous mesenteric glands, and acute peritonitis was present. The right lung was bound down by old adhesions. There was no evidence of enteric fever." Fourteen or fifteen years ago tubercular glands were removed from his neck.

UTERINE CERVICAL POLYPUS UNDERGOING MALIGNANT DEGENERATION.[1]

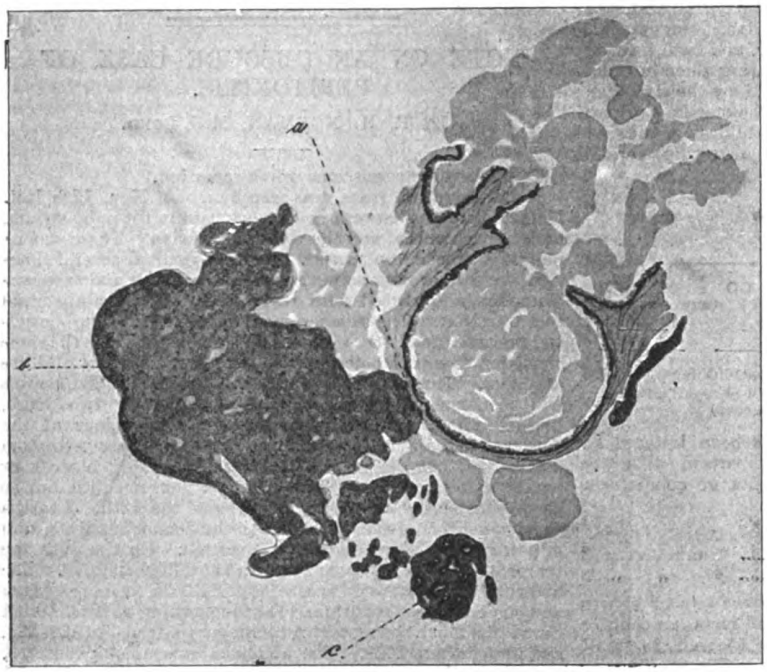
BY H. MACNAUGHTON-JONES, M.D., M.CH., M.A.O. Q.U.I., F.R.C.S. IREL. & EDIN.,
PRESIDENT OF THE OBSTETRICAL AND GYNÆCOLOGICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE.

DURING the last session Mr. J. H. Targett exhibited an adeno-fibromatous polypus of the uterus in which there were undoubted evidences of malignancy. At the time I obtained from Professor Schottlaender microscopical drawings of the sections of a cervical polypus removed when I was at Heidelberg in the late Professor Rosthorn's clinique. I have the privilege of showing these for Professor Schottlaender (Case 1, Figs. 1–4). Such an occurrence is so rare that I feel justified in placing his case on record.

CASE 2. *Carcinomatous polypus of the fundus uteri—the cervix alone being carcinomatous.*—I also show for Professor

[1] A paper read before the Obstetrical and Gynæcological Section of the Royal Society of Medicine on Oct. 6th, 1910.

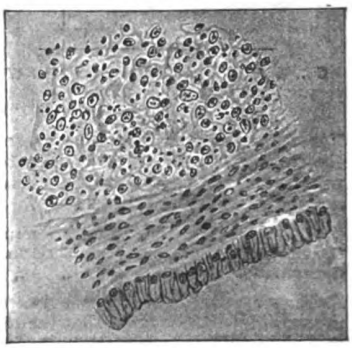
FIG. 1.



Case 1.—General view of the polypus; low magnification. (*a*) (*b*) (*c*) Sections taken at the points indicated in this drawing.

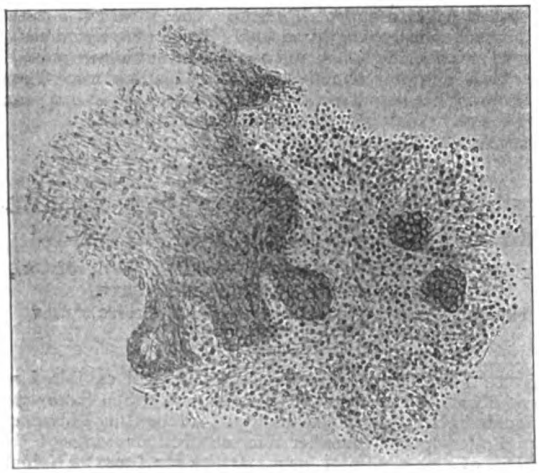
The drawings show (*a*) a cervical gland in its periphery becoming sarcomatous; (*b*) the surface of the polypi covered with a layer of proliferating, metaplastic cylindrical epithelium; (*c*) an island of cervix mucosa with many-layered glandular epithelium filling the gland lumen (arousing the suspicion of early carcinoma) surrounded by a sarcomatous stroma. The patient was aged 70 years; she would not submit to any further operation.

FIG. 2.



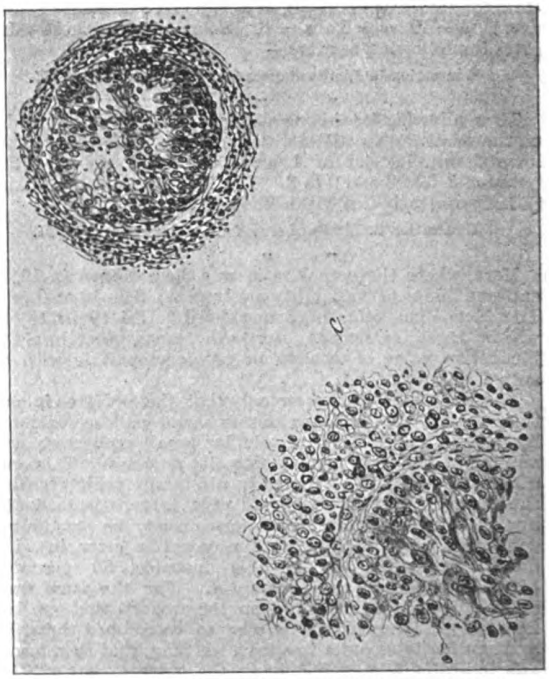
Case 1 (*a*).—Taken through the periphery of a cervical gland surrounded by a cellular stroma becoming sarcomatous.

FIG. 3.



Case 1 (*b*).—Taken from the surface of the polypus. On the surface is a layer of metaplastic cylindrical epithelium, which proliferates inwards. Several detached single alveoli appear separated from the main mass.

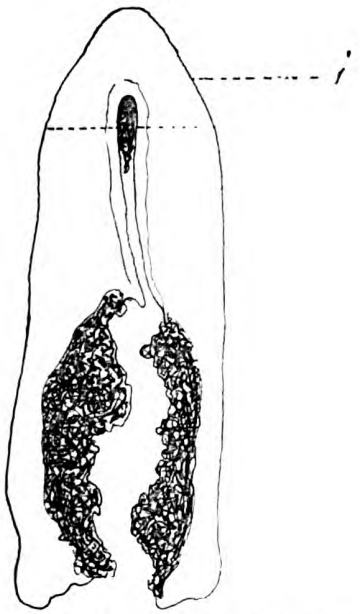
FIG. 4.



Case 1 (*c*).—An island of cervix mucosa with many-layered glandular epithelium filling the gland lumen and arousing the suspicion of early carcinoma surrounded by a sarcomatous stroma.

Schottlaender a drawing of the sagittal section of an entire uterus, the cervix of which was destroyed by a carcinomatous crater, and in the fundus, growing from its summit, a mucous polypus. Section of the latter showed a solid carcinoma. There was no connexion whatever between the polypus and the carcinoma of the cervix, the mucosa of the fundus and body being quite free from carcinoma. The patient was a woman aged 57 years.

FIG. 5.



Case 2.—The cervix shows a carcinomatous crater for which a radical operation has been carried out. A small mucous polypus is seen at the fundus, and sections have been made through the fundus at the level of the dotted line. The sections have not passed through the level of attachment of the polypus, which therefore seems to lie free in the uterine cavity. The polypus is seen to be invaded by strands of columnar-celled epithelium, some of which are solid and others alveolated. The endometrium of the corpus is atrophic; most of the gland epithelium has disappeared or dropped out of the lumina of the glands during preparation.

In connexion with this case I may refer to one brought before the British Gynæcological Society by me—in which a carcinomatous mass filled the summit of the uterus, the rest of the cavity and the cervix being free from malignancy.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON CO POISONING AT THE WHITEHAVEN PIT DISASTER.

BY C. J. J. HARRIS, M.D. DURH.,
AND
EUSTACE THORP, L.R.C.S. EDIN.

ON May 11th, 1910, there occurred in the Wellington Pit, Whitehaven, a disaster by which 136 men and boys lost their lives. Five months afterwards we examined a large number of the bodies. The greater number were much decomposed. From each batch specimens of liver and heart were sent to a physiologist for examination, with the result that the spectroscope proved that in 35 death was undoubtedly due to CO poisoning. This, we think, is a record for the length of time for detection of CO-hæmoglobin. In the case of many other bodies in which we suspected death to have been due to CO, but in which it was not proved, it was supposed that the compound had been dissociated by heat and bacterial agency. The heat was so intense at certain parts of the mine that iron bolts were melted. On examining the bodies post mortem we noticed that all were well nourished. The viscera showed great decomposition. The liver in all cases was in a state of excellent preservation, the heart in fairly good condition though flabby, and the lungs were the most decomposed organs. The muscles and intestines were of a bright pink colour, which quickly turned muddy-brown on exposure to air. Certain of the bodies showed signs of burning, extensive charring being present on all parts, the scalp in some instances being entirely carbonised. In one case a mass of bones and white ash were found: these were quite calcined and resembled the shanks of clay pipes, the only perfect bones being the temporals, some carpal and metacarpals, and one or two vertebræ. The remains were found in most cases in attitudes of repose and in large groups, and in many instances so decomposed that one of us (C. J. J. H.) found it necessary to order the bearing party to place shovels under the head, shoulders, hips, and legs to prevent them from falling apart. From our investigations the causes of death were classified thus:—

Undoubted CO poisoning	35
Burns and shock	30
Violence of explosion	12
Suffocation (smoke fumes and probably CO) ...	38
Burns and suffocation (not CO)	4
Presumably burns, shock, and suffocation ...	1
Suffocation (probably CO)	12

Thus we believe that 85 of the victims met their death from CO poisoning and, as mentioned above, in 35 this was definitely proved. It may be interesting to add that the remains were found about 600 feet down, the nearest being three miles from the shaft. Falls and gas had to be encountered, so that the men had to move the bodies as expeditiously as possible, many of them being "groggy" on their legs from the inhalation of the gaseous fumes. Formaldehyde was the disinfectant used.

Whitehaven.

NOTE ON A CASE OF LOSS OF VISION FOLLOWING A SMALL DOSE OF SANTONIN.

BY E. J. BAXTER, L.R.C.P. & S. E.

THE following sad case of poisoning by half a grain of santonin may be of sufficient importance to make it worthy of notice in your valuable journal.

A girl, about 5 years of age, suffering from roundworms and threadworms, was brought here for treatment. My assistant gave her a dose of santonin in castor oil, which, however, her mother says, she vomited almost immediately after leaving the dispensary. Three days later she brought the child again for treatment, as beyond the vomiting caused by the castor oil the first dose had had apparently no effect. I then repeated the medicine, giving half a grain of santonin in about 2 drachms of castor oil. This was retained for about eight hours, when it acted, bringing away a large number of threadworms, together with a few roundworms. The mother says that the child then became very weak and for two days lay as if she were dying, without moving her limbs or opening her eyes. But on the third day she began to recover and it was then discovered that she was quite blind. It was not till three weeks later that the parents, who live about 12 miles away on the top of the mountains, again brought the child to me. On examination I found that the girl was, as the mother stated, quite blind. Hoping that under treatment the sight might be restored, I got the mother to remain here with the child for about six weeks, at the end of which time, as the girl was still blind, she returned home with her. Though more than three months have elapsed since the child was brought here for treatment, I have not heard that the sight has been recovered.

I would like to know if any of the readers of THE LANCET have had a similar experience from so small a dose, and what treatment has been found beneficial in such cases. Stillé cites a case in which a child aged 6 months took 5 grains of santonin instead of 3 grains which had been ordered, and becoming amaurotic did not recover sight for two months. Hughes says, "it must be remembered that 2 grains have proved fatal to a child." In THE LANCET it has been recorded that 1½ grains caused convulsions in a child.

Dar-es-Salaam, G. E. Africa.

SURGICAL SECTION.

Fractures near Joints.

A MEETING of this section was held on Nov. 29th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

The adjourned discussion on the paper by Mr. Robert Jones (Liverpool) on the Treatment of Fractures in the neighbourhood of Joints, which was published in THE LANCET of Nov. 19th, p. 1479, was opened by Mr. HERBERT J. PATERSON, who said that Mr. Jones had pointed out with regard to the treatment of fractures that there were two schools—one relying upon operative, and the other relying upon mechanical methods of treatment. The discussion indicated that there was less difference in principle between the two schools than was generally believed. Mr. Jones had told them that if he could not put a fracture into perfect alignment he operated. That was exactly the same position as that taken up by Mr. W. Arbuthnot Lane. His own practice was similar. The debate would not have been in vain if the principles upon which fractures should be treated had been clearly laid down, and it was interesting to learn that Mr. Arbuthnot Lane and Mr. Jones were in agreement as to first principles concerning fractures. There was one point upon which Mr. Jones had not touched. As Mr. Jones had observed, impairment of function was much more serious than any mere outward change of shape; but change of shape might be a serious matter for the surgeon. Whether they liked it or not, they had to recognise that since the introduction of X rays the public had become increasingly critical as to the results obtained in the treatment of fractures. The courts of law now were not satisfied that all possible had been done if the X rays demonstrated a result anatomically bad, however good the functional result might be. He was not arguing that that attitude was right, but he wished to point out that as the courts of law took that view surgeons must either accept it or try to alter it. It was interesting to learn from Mr. Jones that the use of a double inclined plane for fractures of the femoral condyles was based on a superstition, but at the same time he (Mr. Paterson) did not think that Mr. Jones's analogy with the treatment of an osteotomy of the femur was a true one. In a traumatic fracture there was much laceration and tearing of muscles, and, as a consequence, much greater displacement, than was the case after section of the bone with a chisel. Consequently, after osteotomy they would not expect to have to use a double inclined plane any more than they would think it necessary to use a screw or a plate. He (Mr. Paterson) confessed that his experience of the treatment of these fractures by splints and extensions had been very unsatisfactory, and although he pleaded guilty to having designed a special splint for these fractures he had come to the conclusion that in most cases an operation gave the best results. He agreed with all that Mr. Jones had said as to the harmful effects of early passive movements in fractures about joints, and believed that many of the bad results which followed these injuries were the outcome of the present advocacy—he had almost said mania—for early passive movement. He was glad to learn that Mr. Jones regarded as a superstition the belief that a joint would remain permanently stiff because it was kept immobile. There could be little doubt that many erred on the side of too short a period of fixation, and he thought that the periods of union of fractures laid down in text-books were too short. If at least a week or ten days were added to each period given they would not err on the side of too prolonged treatment. He supposed that some of the most troublesome fractures with which they had to deal were those about the ankle-joint. Few surgeons would assert that the treatment of these fractures was entirely satisfactory. Mr. Clinton Dent had told them that he had never known a member of the police force able to return to duty after a Pott's fracture. Correct alignment and accurate adjustment of the parts in this fracture was of such importance that he thought most cases were treated best with screwing or plating. He gathered that Mr. Jones's practice was tending in the same direction. It was probable, however, that the frequency of indifferent results was due to insufficiently prolonged treatment. They were apt to be satisfied if the patient left the hospital with a well-united, well-set limb, but they had often little idea as to the ultimate results. As Mr. Jones had suggested, the patient got about too soon, and a condition of valgus was the consequence. It had always struck him (Mr. Paterson) as remarkable that even the most vigorous opponents of the open treatment of fractures were usually enthusiastic advocates of operation in cases of fracture of the patella. This attitude did not seem readily explicable. Firm fibrous union of a fractured patella was the rule when treated without operation. There was no question of correct alignment, and it was not of great importance whether or not the fragments be brought into close apposition, and the fracture did not result in any shortening or deformity. No one could assert that there was absolutely no risk of sepsis in opening a knee-joint. And yet many of those who regularly operated in fractures of the patella maintained that it was unjustifiable to operate on a fracture of the femoral shaft. Personally, he considered that operation was indicated more certainly in the case of a fractured femur than in that of a fractured patella. In the case of the femur correct alignment was of the utmost importance. For his own part he did not advise routine operation on fractured patellæ because he believed that as good a result could be obtained without as with operation.

Mr. DOUGLAS DREW said that they had heard so much recently about the necessity of operative measures in the treatment of fractures that it seemed to him that the paper by Mr. Jones demonstrated what excellent results might be obtained by manipulative means in the hands of a skilful surgeon. Mr. Drew recognised that some of the fractures under discussion could only be treated satisfactorily by operative means, and believed that in the majority of fractures in the vicinity of joints an entirely satisfactory result could be obtained by manipulative means alone. Continuing, he observed that those who favoured operation naturally thought that they could obtain better results by so doing, and he thought they were liable to overlook the fact that even after operation the result, as demonstrated by the X rays, was by no means anatomically perfect, and often it did not appear to be better than in a similar case treated without operation. Mr. Drew thought that there was a tendency to minimise the fact that these procedures were often of a severe nature and, even with the most perfect technique, a failure from sepsis might occur with disastrous results. He thought that operation should be reserved for those cases in which it is impossible to get the fragments into a good position and in which impairment of function was certain to follow. His experience lay chiefly with children, and in 13 years as surgeon to the Queen's Hospital for Children he had seldom found it necessary to operate. His usual practice was to commence massage within a few days of the accident, and if there was no tendency to displacement of the fragments gentle passive movements should not be delayed; but he did not agree with Mr. Jones in thinking that they caused additional trauma and increased the stiffness provided they were carried out with sufficient care. The best guide was the absence of pain; he agreed that active movements should be encouraged, but in children this was one of the difficulties, and it was best overcome by showing the child that the injured limb could be moved without causing pain. With regard to separation of the lower epiphysis of the humerus, full flexion of the elbow sufficed to reduce the deformity in most cases, but sometimes, owing to the swelling, it was not possible to flex to the desired degree. Separation of the lower epiphysis of the femur with marked displacement was sometimes a very difficult injury to treat, and might necessitate operation. Mr. Drew concluded by describing an example of an extreme form of this injury, in which the epiphysis was displaced forward on to the anterior surface of the shaft and rotated so that the articular surface looked directly forward. It was found impossible to reduce this except by operation, and it could not be retained in position without the use of Lane's plates.

Mr. C. H. FAGGE said that it would be generally agreed that the great difficulty in restoring the normal alignment of such fractures was the small size of the articular fragment and the consequent inability of exercising upon it sufficient

leverage to bring its broken surface into true relation with that of the larger fragment; he therefore held that this class of injury was particularly suitable for treatment by open operation as introduced by Mr. Arbuthnot Lane. The necessity for accurate replacement varied in different positions of the body and also with the occupation of the patient, but was fundamentally called for in treatment of the common fracture of the region of the ankle—known as Pott's fracture whether of the adduction or abduction type—because of the serious mechanical disabilities such as flat foot and genu valgum which followed the usual inability to reduce the deformity by other means. Similar injuries in boys resulted in separation of the lower tibial epiphysis with fracture of the fibula, and in his experience operation alone restored the parts to their normal relationship; he had recently operated on such a case in which the diaphysis so far overhung the epiphysis and tarsus that an effort had been made in another hospital to reduce it as a dislocated ankle. He also held that many cases of supracondylar fracture of the humerus could not be replaced by manipulation, and showed some X ray photographs contrasting the position after manipulation under an anæsthetic with the real replacement fecured by open operation. In the common supracondylar sracture operation allowed of the evacuation of blood from the fossæ around the elbow and thus minimised the tendency to callus formation in this position, which later so frequently resulted in limitation of movement. Of all injuries in the upper extremity calling for operation Colles's fracture and separation of the lower radial epiphysis were the most common, and in these, as in many of those affecting the lower end of the humerus, replacement was all that was required, as when replaced the fragments remained in good alignment. Fractures near the shoulder did not usually demand operation, because movements of the scapula vicariously replaced those lost at the shoulder. X rays were of great value, especially in warning the surgeon in cases where the bones were so frail, as indicated by abnormal translucency to the rays, that screws could not obtain a firm hold.

Mr. W. H. CLAYTON-GREENE said that he did not agree with the views of Mr. Jones as to early movement. The first object to attain was rest for the injured parts, and yet they were told to commence movements at the end of the third day. Mr. Clayton-Greene said he was strongly opposed to such methods, and declared that except in the hands of most specially skilled people much harm resulted therefrom.

Mr. H. P. SYMONDS, Mr. A. E. JOHNSON, and Mr. A. J. WALTON also spoke, and Mr. R. J. GODLEE described how he had used an ivory peg in a case of fracture of the neck of the femur.

Mr. JONES, in replying on the discussion, thanked the Fellows for their kindly criticism, which showed that there was not any wide disagreement. He thought that if speakers gave their experiences it would teach extremists that there was more than one way of achieving the same result. In the hands of a clean surgeon he would not mind having almost any bone in his body wired. Again, if he could be assured of a good functional result without operation, he would be willing to forego a more artistic one. He had not known of a description of fractures of the spine of the tibia, and he thanked the President for the description of his case. He agreed one often found a rounded condition of the neck in traumatic coxa vara, which assured one that there was antecedent softening of bone. He had skiagrams showing separation of the epiphysis, starting from below as a little V-shaped space which gradually extended, resulting finally in a complete separation, the neck ultimately becoming rounded and resulting in a typical coxa vara. With regard to pegging or wiring where there was separation of the head of the bone in a young adult, he thought it unnecessary; if it were well abducted and extended there would be a good result. If it were decided to nail through the trochanter it should not be done without first exposing the joint. With regard to avulsion of the tibial tubercle, he had several photographs showing separation in various stages—the later photographs in some cases showing the separation more marked. Unless treated by complete rest, there was likely to be much thickening over the tubercle and tenderness on pressure. That was best treated by making a linear incision into it with a chisel, just as in the case of sclerosed bone, to relieve tension. He had seen this year two cases of Volkmann's ischæmic paralysis, so it did not yet belong to the past entirely. It took place as often from pressure within the arm as from pressure from without it. Cutting down on each tendon and lengthening it was not so effective as a simple procedure which he himself had demonstrated. It had been suggested that Bennett's fracture was never troublesome, but the speaker regarded it as one of the most difficult to treat mechanically, and he would be glad to hear what measures could be taken in that condition. Incomplete mobility so often occurred that he sometimes had to cut down to remove the fragment. Mr. Fagge said that Colles's fracture was very suitable for plating, but Mr. Jones thought Colles's fracture was one of the most amenable to simple treatment. Colles's fractures which resulted badly did not redound to the credit of either the surgeon or the patient. With reasonable coöperation there should be no bad result in cases of the kind. In dealing with acute flexion it was not sufficient to put the arm into an angle of 45°, but the flexion and supination should be complete, the hand almost resting on the shoulder.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Congenital Obliteration of Bile-ducts with Hepatic Cirrhosis.—Exhibition of Cases.

A MEETING of this section was held on Nov. 25th, Dr. E CAUTLEY, the President, being in the chair.

Dr. F. PARKES WEBER and Dr. G. DORNER communicated a paper on Congenital Obliteration of Bile-ducts with Hepatic Cirrhosis. The case was that of a female child, aged 6 months at the time of death, who had jaundice of the obstructive type with complete absence of urobilin (and urobilinogen) from the urine and the fæces. The liver and spleen were both considerably enlarged. The necropsy showed that the distal part of the hepatic duct, the cystic duct, and the common bile-duct were represented by connective tissue cords without any lumen, but the cord representing the choledochus could not be traced as far as the duodenum. Sections of the connective tissue cord showed not only complete absence of any biliary channel, but furnished no evidence that there ever had been any lumen. Perhaps the term "congenital atresia of bile-ducts," as suggested by Lavenson, was therefore more suitable for the present case. The gall-bladder contained a little slimy, colourless fluid. In the spleen the pulp tissue and supporting fibrous tissue were increased in amount. The liver was green in colour, the cirrhosis being of the unilobular (interlobular) type, which can be experimentally produced by ligature of bile-ducts (obstructive "biliary cirrhosis"). The liver and microscopical sections from the case were exhibited.

Dr. J. L. BUNCH showed a case of Morphœa in Band Form in a girl aged 5 years. Three years ago the child fell and bruised her forehead. Shortly afterwards a patch of sclerodermia appeared on the right temple, gradually spreading upwards on to the scalp and downwards on to the nose. Over the affected area the hair had disappeared and the skin was tense and atrophic.

The PRESIDENT exhibited a case of Splenic Enlargement in a boy, aged 6 years, whose family history was good and free from tuberculosis and syphilis. Three weeks previously sudden pain and swelling occurred in the ankles, which rapidly subsided. The eyelids and feet at first were œdematous; the urine was normal. The spleen was considerably enlarged and the liver slightly so. The blood showed a leucopenia. In the discussion both tubercle and syphilis were suggested as a diagnosis.

Mr. H. S. CLOGG showed a case of Extensive Necrosis of the Lower Jaw in a girl aged 7½ years. Two months previously the child had toothache and swelling of the face and submaxillary regions. The mouth could only be opened half an inch, and the tissues on the floor were indurated. The constitutional disturbance was great, the temperature rising to 103° F. On the gum and lower lip were large sloughs and a copious purulent discharge. The lower central incisors fell out, and the whole of the alveolus in this region was exposed. Other loose and carious teeth were removed, and antiseptic mouth washes were used with little improvement. As the pus yielded a pure streptococcus 10 c.c. of serum were given with marked benefit. Four other injections caused a fall of the temperature to normal on the tenth day. The child rapidly improved in health, but the sequestrum was still firmly attached.

Dr. T. R. WHIPHAM exhibited a case of Patent Ductus Arteriosus with deficient interventricular septum in a girl

aged 11 years. There was a history of cardiac distress since infancy, but there was no "clubbing" and no cyanosis except on occasions. The dulness of the heart and great vessels was increased to the left. At the apex there was a blowing systolic murmur, and over a localised area in the pulmonary region there was a continuous thrill and a loud "churning" rumble throughout systole and diastole. There was no evidence of enlarged glands.

Dr. PARKES WEBER showed: 1. A case of Nævus Verrucosus Linearis in a boy aged 3½ years. The skin of the trunk, neck, and extremities was largely affected with pigmented and verrucose nævus. The abnormality began when the child was seven months old. 2. A case of Congenital Transposition of the Viscera in a girl aged 10 years. Clinical signs and a skiagram showed a complete transposition of all the viscera. There was no valvular disease of the heart.

Dr. F. LANGMEAD showed: 1. A case of Rheumatoid Arthritis in a boy aged 13 years. The condition began two years ago and the hips, knees, ankles, elbows, wrists, and hands had been affected. The axillary glands were slightly enlarged, but no enlargement of the spleen had been detected. Skiagrams showed that the enlargement of the joints was periarticular. Improvement had been brought about by treatment with thyroid extract, which was given on account of the mother having had myxœdema for 15 years. 2. A case of Malformation of the Heart in a male infant, aged 8 months, who was cyanosed but did not show any appreciable "clubbing." The heart was enlarged to the left; a systolic bruit was audible over the cardiac area, especially at the xiphisternal junction and was accompanied by a thrill. The condition was possibly one of deficient interventricular septum.

Mr. O. L. ADDISON showed: 1. A case of old healed Tuberculous Disease of Knee-joint with increase in length of the limb. The boy first had signs of tuberculous disease of the knee in 1906. He was treated for six months, and afterwards had a Thomas's splint. For the last eight months he had been walking about and was free from recurrence. Movement in the joint was almost perfect, but the leg was one inch longer than the other, the femur and tibia being each half an inch longer. Skiagrams showed increased translucency of the tibial and femoral epiphyses with some irregularity of outline. 2. A case of Sarcoma of the Femur in a girl aged 1½ years. The growth, which was in the right femur, had been noticed for two months and did not appear to penetrate the bone (X rays). The liver and spleen could both be felt, and there were a few small glands in the left groin. It was not proposed to operate. 3. A case of Interstitial Hernia in a boy, aged 2 years, who had been operated upon for left inguinal hernia. There was a subcutaneous hernia of the size of a pigeon's egg above Poupart's ligament on the same side, and the left testicle was undescended.

Dr. G. A. SUTHERLAND exhibited a case of Cardiolysis for Adherent Pericardium in a boy aged 6 years. Eleven months ago the patient was admitted to hospital suffering from subacute rheumatism and rheumatic nodules. There was bulging of the præcordial region and a heaving impulse. The heart was greatly enlarged and a double murmur was audible at the apex. The boy became a chronic invalid, and adherent pericardium with dilatation and hypertrophy was diagnosed. Six months ago Mr. W. H. Clayton-Greene removed parts of the cartilages of the fourth to seventh ribs at the sternal junction to allow more freedom of action for the heart. Since then the boy had had one attack of cardiac failure, but on the whole he had been better and much more active.

The paper and cases were discussed by the PRESIDENT, Dr. J. W. CARR, Dr. SUTHERLAND, Dr. H. D. ROLLESTON, Dr. J. D. ROLLESTON, Dr. J. PORTER PARKINSON, Dr. A. E. GARROD, Dr. T. R. WHIPHAM, Dr. E. I. SPRIGGS, Dr. F. W. HIGGS, Mr. W. MILNER BURGESS, and Mr. J. P. LOCKHART MUMMERY.

MEDICAL SOCIETY OF LONDON.

Heart Strain and Dilatation.

A MEETING of this society was held on Dec. 5th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. W. COLLIER (Oxford), in resuming the adjourned discussion on Dr. F. J. Goodhart's paper (see THE LANCET of Dec. 3rd), said that unfortunately heart strain in athletes had been on more than one occasion of late years the subject of discussion in the columns of the lay press. Anyone would gather from those discussions that the athletic competitions at public schools and universities were a potent cause of life-long injury to many boys and youths. But the real facts of the case were brought out in an inquiry made among the medical officers of schools and universities, who were almost unanimously of opinion that such care was taken in the matter that there was very little injury done.

Dr. SAMUEL WEST said that strain was a term in common use. A man was said to be working under great pressure or strain, nervous or physical, and when overworked to be suffering from nervous or physical breakdown. Strain in its clinical sense was that breakdown or overstrain. Cardiac strain in the same way might be nervous or physical. The two groups should be sharply distinguished, for the physical strain had its seat in the heart and nervous strain outside the heart in the nervous system. It might be stated that those in whom the nervous symptoms were most marked were least likely to show signs of organic disease. It would be well if the distinction could be marked by different terms, for heart strain was generally assumed to imply muscular failure. For the nervous group there was no satisfactory name. Functional affection or cardiac neurosis were at once too indefinite and too wide. The diagnosis between the two groups was of great importance, but it was just there that the difficulty came in, and mistakes were common enough to destroy confidence and necessitate caution. The cardiac symptoms were the same in both groups—viz., pain, palpitation, and shortness of breath. To those were added in the cardiac group the physical signs of dilatation—viz., displacement of the apex, increase of cardiac dulness and movement. The difficulties of diagnosis were increased by the fact that the two classes cut into one another. Thus the general ill-health accompanying a nervous breakdown might affect the heart muscle and make it to be feeble and to dilate. On the other hand, nervous symptoms might be added to the symptoms of organic disease and greatly aggravate the patient's suffering. No organ was more subject to nervous influence than the heart. Every one was familiar with the bursting feeling in the chest, the choking in the throat, and the violent palpitation of a nervous man who had to speak in public. Training was not merely muscular but nervous too, and in that case the nervous system began its work too soon. It was not till the heart was hard at work that it steadied down and relief was obtained. That was a good illustration of the beneficial effect of treating nervous cardiac over-action by work.

Dr. WALTER BROADBENT said there was one interesting method of examining a case of supposed heart strain which had not been referred to—that was by taking a tracing of the jugular pulsation in the neck with Mackenzie's polygraph. As far as his experience went, he had found that in cases which were functional or due to some form of dyspepsia there was no variation from normal in the jugular tracing, but in genuine cases there might be one of two conditions—either a very large auricular wave or a ventricular wave higher than the auricular. When the auricular wave had been large, presumably showing hypertrophy of the auricle, relief of symptoms had quickly followed the giving up of violent exercise for a week or two and the taking of a tonic. The patient had been able gradually to resume his old mode of life and the playing of games with only a little moderation. When the ventricular wave had been higher than the auricular, though rest, graduated exercise, and treatment had changed the character of the jugular curve and made the ventricular wave much smaller than the auricular, there had been great liability to relapse on any unusual exertion. Those jugular tracings were particularly useful when there was very little dilatation of the heart, and that perhaps masked by emphysema. When there was definite dilatation, it seemed to him better to put the patient to bed and give calomel and cardiac tonics, in order to see how much the heart would contract. He had seen the apex beat come in over an inch in a week. Massage was useful to keep the muscles in condition. As soon as the size of the heart appeared to be stationary, the patient could be gradually got on to his feet while the massage was continued. Afterwards he had a great belief in the Oertel system of graduated walking up hill. That was very easy to carry out in a hilly place like Brighton, every day one lamp-post further up the street, or, if the hill was steep, taking two to three days to reach the next

lamp-post. He had seen a gentleman last week who for a year up to last January had not walked 200 yards without getting out of breath; he was only 40 years of age, but had a dilated heart, said to have been brought on by sudden exertion. He had followed the Oertel system diligently, and now told him that he had reached 500 feet of altitude and six miles of distance daily. During the whole time the size of the heart had steadily decreased. That was an infinitely cheaper form of treatment than the Nauheim, and in his experience had given quite as good results.

Dr. ALEXANDER MORISON thought that Dr. Goodhart had rendered a public service in opening this discussion. He considered that the public had been unduly familiarised with the ideas of cardiac dilatation and strain during the last 20 years. While, however, he deprecated the attitude of the alarmist in medicine, he thought there was also some danger in that of the optimist. Hearts did dilate or become inefficient without gross organic disease, and it was quite possible unduly to minimise the importance of such conditions. Variations from the normal standard had to be examined carefully before being dismissed as unimportant. He did not think the argument from the right to the left heart was on all fours. The conditions involved were so different. While he regarded with suspicion all mitral leakages, he considered tricuspid leakage and right ventricular distension common and often physiological. He agreed with Professor Keith that left and right apical displacement was usually governed by the distension of the opposite auricle. Right auricular engorgement was common and often physiological, even in the presence of left ventricular disease; and the displacement of a variable apex beat to the left, also frequently physiological and of little moment. On the second head of the discussion concerning the neural origin of some persistent irregularities of the heart, he agreed with Dr. Goodhart, but considered that the question was now so much debated and of so interesting a character that it could not be adequately discussed as a rider to the general theme under consideration.

Sir JOHN BROADBENT agreed with Dr. Goodhart that the importance of percussion of the area of cardiac dulness as a means of estimating strain or dilatation of the right ventricle was greatly over-rated. It was not rational on percussing out the area of cardiac dulness for the first time in a new patient and finding that it exceeded somewhat the normal limits to say that the heart was necessarily dilated and required treatment. An athletic individual would naturally have a larger heart than an ill-developed bookworm, the increase in size being the physiological response to the increased demand. It was not the size of the heart as estimated by percussion that mattered, but its functional capacity that was all important. In aortic incompetence a certain amount of dilatation followed by hypertrophy was a part of the compensatory change. In diphtheria, in which a fatal syncopal attack was especially liable to occur, there was frequently no appreciable evidence of cardiac dilatation as shown by percussion. More valuable evidence as to the functional capacity of the heart could be gathered from the pulse, the character of the heart sounds and of the apex beat, or from symptoms such as breathlessness or præcordial pain on exertion, than from mere mapping out of the cardiac dulness. It was advisable in speaking of cardiac dilatation to distinguish between dilatation of the right side of the heart and that of the left. As a result of severe exertion the right side of the heart might temporarily be over-distended and a systolic tricuspid murmur make its appearance, but equilibrium would soon be restored in a healthy heart. It was a more serious matter when a systolic mitral murmur set in after exertion, as that indicated dilatation of the left ventricle. The important etiological factor in dilatation of the heart was loss of tone in the cardiac muscle. Such loss of tone might result from various toxæmias, and the dilatation of the right ventricle that ensued might be very considerable. This was especially the case in rheumatism, and here there was frequently not merely loss of tone, but extensive damage to the cardiac muscle, which would account for the extensive degree of dilatation met with in this affection. Ptomaine poisoning and auto-intoxication might also be responsible for such loss of tone. An atonic condition of the cardiac muscle might also be part and parcel of the general loss of tone throughout the muscular system due to exhaustion of the nerve centres from overwork or prolonged mental anxiety and strain, or some severe shock. In such conditions undue exertion might readily give rise to acute dilatation. The following were instances he had seen. A solicitor, greatly overworked, found that he could not play golf as usual on a Saturday without getting short of breath and very soon tired. He was found to have a soft systolic mitral murmur and an apex beat half an inch outside the nipple line. A strong athletic man after an accident in which a depressed fracture of the skull necessitated trephining, found that after his recovery from this he was short of breath on slight exertion and generally slack. On examination a similar condition of heart was found. In both these cases change to a bracing climate with rest at first, not in bed but simply taking things easy, followed by graduated walking exercise, led to complete recovery and all disappearance of the cardiac murmur. A large proportion of symptoms often attributed to cardiac dilatation, such as palpitation and other disorders of rhythm, fainting attacks, and various subjective sensations of pain and discomfort in the præcordial area were "neurons" of the heart or reflex disturbances which were commonly met with in highly strung individuals or in cases of nervous breakdown after prolonged strain or anxiety.

Dr. CHARLES W. CHAPMAN said the importance of dilatation depended upon (1) the age of the patient; (2) the general physical condition; and (3) the previous history. When the patient was young and vigorous and had his heart strained then, although he had some dilatation, irregular action, and possibly a soft systolic mitral murmur, a short period of rest would in most cases be all that was necessary. In patients past middle life, although they might up to the time of the strain hold a clean bill of health, the prognosis and the length of rest necessary would depend upon the state of the vessels and of the more important viscera, especially the kidneys. He had recently seen a gentleman about 60 years of age, who had severe cardiac symptoms after dancing. He had never been ill. The serious nature of the case was not recognised and he was allowed to travel. On his arrival home he was very ill, and when seen by Dr. Chapman in consultation his heart was greatly dilated, and he had all the signs of back pressure, to which he rapidly succumbed. Had that patient been put to bed at once and had complete rest he would in all probability have got better. With reference to the previous history, that of syphilis was of paramount importance, particularly if aortic as well as cardiac dilatation existed, when prolonged rest, in conjunction with treatment, was of vital importance. As to whether the limits of cardiac dilatation could be defined with any approach to accuracy, he was confident it could by percussion properly performed by one practised in the art, though something of a musical ear was a great assistance. At the same time, to pretend to make measurements to a hair's breadth was as ridiculous as it was useless.

Dr. LEONARD GUTHRIE agreed with Dr. Goodhart that the physical signs supposed to indicate heart strain and dilatation—namely, slight displacement outwards of the apex beat, an impulse varying in force and direction and speed, irregular and intermittent action, together with the presence of bruits, systolic in time over the pulmonary valves, and sometimes audible from the apex to the level of the pulmonary area, varying with the patient's position, were unreliable as evidence of cardiac dilatation. He thought, however, that they might be regarded as evidence of past strain and dilatation, and of potential dilatation should the patient indulge in over-exercise. It did not follow that because signs of dilatation were absent at one time that they had not been and would not be present at another. He agreed again with Dr. Goodhart that the symptoms—fainting attacks, pains over various parts of the præcordial area, sighing respiration, palpitation, collapse with sensation of impending death, and extreme lassitude after smallest exertion—were not those met with in cases of cardio-valvular disease. Still, the symptoms were no doubt of cardiac origin in spite of the fact that the patient was as a rule neurasthenic to an extreme degree. He did not think it altogether safe to treat such patients as neurasthenics without reference to their cardiac condition. If one reassured them and said there was nothing the matter with their heart they were extremely likely rashly to over-exert themselves and thus make matters worse, as in one of Dr. Goodhart's own cases. He believed that the most frequent cause of cardiac strain and primary dilatation was

over-exertion following an attack of influenza. Although, as Dr. Goodhart stated, treatment by rest might be overdone, he was convinced that in all acute cases it was necessary for at least a month. Gentle and graduated exercise might then be prescribed, but athletics and all prolonged or severe physical exertion should be forbidden to those who had once suffered from definite symptoms of cardiac strain and dilatation.

Dr. F. PARKES WEBER having spoken, Dr. GOODHART replied, and the meeting concluded.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Transperitoneal Cystotomy, with Report of a Case.—Diagnosis of Renal Calculus.

A MEETING of this section was held on Nov. 18th, Mr. R. H. WOODS, the President, being in the chair.

Mr. SETON PRINGLE read a paper on Transperitoneal Cystotomy for Tumour of the Bladder, with Report of a Case. He gave a history of this operation, and compared the results obtained by it with those obtained by operating by the suprapubic route. He advocated this method in all cases of tumour, except those situated at the apex of the bladder. He described the operative technique in detail, and illustrated the various steps by lantern slides. The paper concluded with a report of a case of papilloma successfully dealt with by this route by Mr. Pringle.—Mr. A. J. BLAYNEY said that he had used the method twice, and he could confirm what Mr. Pringle had said with regard to the excellent view of the bladder obtained. The after-treatment he had used was to drain the bladder for a few days, and afterwards urine was passed quite readily.—Mr. JAMESON JOHNSTON said he had not done the operation, but it appealed to him as being scientific, and based on anatomical principles, and one certain to be very useful in the future, but he would not use the transperitoneal method unless he thought the other method was not sufficient.—Mr. C. A. K. BALL said he had attempted to do transperitoneal cystotomy in the case of a man, aged 56 years, who had a malignant tumour of about the size of a five-shilling piece involving the left ureter. On opening the abdomen it was found that there was a mass of secondary growth completely adherent to the iliac vessels. The case was therefore inoperable and the abdomen was closed. He was much struck with the splendid access to the bladder that was obtained. Although in a thin patient it was one of great ease, in a fat person there was difficulty in keeping the intestines back before opening the bladder, but when opened the tumour was easily removed and the result was satisfactory. He did not gather whether Mr. Pringle had used the valuable aid of the electric head-lamp which had been brought to his notice by the President. With the head-lamp one was able to work with a smaller incision in the bladder, and the interior was readily illuminated.—Mr. W. I. DE C. WHEELER said that, considering the mortality of the removal of benign tumours, it was time some new methods of technique were developed. He had been impressed with Mr. Pringle's work, and on his advice had used the transperitoneal method. The operation had great advantages over the ordinary suprapubic method, and he would be inclined to use it in every case of tumour of the bladder where there was any difficulty in the removal of the tumour.—Mr. K. E L. G. GUNN asked if Mr. Pringle meant that the operation was to be done in all cases of the bladder or only in carcinoma. He had operated on eight cases of malignant growth in the bladder. In one of the cases he had not recognised malignancy before the operation and found the growth too late to do anything. In two cases he did the transperitoneal operation, and in one case had to replant the ureter higher up in the bladder wall. The patient died five years after the operation. The second survived the operation, but died from recurrence five months afterwards. In four cases of radical suprapubic operation, one died 12 months later, one died in nine months, one was still alive three years after operation, and another four years. One should adopt whatever method was most convenient to get at the growth. No matter how carefully they sutured, there was a danger in the transperitoneal method of leakage of urine.—The PRESIDENT said that, in his opinion, no cavity operation could be as well done without an electric head-lamp as with it, but for the purpose they must have a theatre that was not too highly lighted. If they had a subdued light sufficient to enable the assistants to do their work, and others to see what they wanted to see, and they used a suitable lamp with a large concave reflector that could be varied, he was of opinion that, no matter what the operation was in a cavity, they would be able to see ever so much better, and they would never go back to the old plan that compelled them to put their head between a light and the cavity.—Mr. PRINGLE, in reply, said he did not advocate the operation for all tumours. He thought it had not been done often enough to be quite sure of its mortality. He was inclined to advocate it in all cases except those of tumour situated near the apex of the bladder. One would think that with the transperitoneal operation, even with the risk mentioned by Mr. Gunn, they should have a less mortality than the immediate mortality of 10 per cent. with the suprapubic method. One could form a fair idea of malignancy with the cystoscope, but it was not sure, and the transperitoneal method enabled them to deal much more radically and rapidly with the tumour. He had good light in his case, and he thought the chief point was to get the patient into a very high Trendelenburg position so that he was almost vertical, and the light of the theatre window shining in. He did not personally feel the need of a head-light. As regards the risk of the operation, a great many of the 23 cases reported by him, from American literature, were septic bladders. Richardson in America had taken out two large stones in two cases in which the bladder had tightly contracted down. He did the transperitoneal operation in both cases, the bladder being intensely septic, and both recovered without peritonitis.

Mr. MAURICE R. J. HAYES in a paper on X Rays in the Diagnosis of Renal Calculus laid special stress on the necessity for thorough evacuation of the intestines in order to obtain a satisfactory radiogram. A description of a simple method of obtaining compression of the kidneys by means of an ordinary girth was given. The various causes to which errors in diagnosis may be due were discussed, and radiograms illustrative of these were shown. The use of radiography as the only method of diagnosis of calculi was not recommended, but taken in conjunction with the ordinary methods of diagnosis it furnished more valuable information than could be obtained in any other way.—Dr. W. S. HAUGHTON said he did not think that X rays should be used to replace the ordinary methods of clinical examination, but rather to confirm them. He had never known a Roentgen picture to make a mistake with regard to a stone in the kidney. With regard to controlling the respiratory movement of the kidney, the strap mentioned was an admirable addition to the work. There were other methods of extreme usefulness.—Sir JOHN LENTAIGNE said the X rays were so valuable a help that they were tempted to drop the more laborious methods of diagnosis.—Mr. HAYES, in reply, said he had invested so much in apparatus that he was afraid to put more money into the Albers-Schönberg compressor. He thought it was a cumbersome and heavy affair, and everything could be obtained by a contrivance at an expense of 3*s*. 6*d*. He had recently used a rubber air-pillow, and found that he got the shadow of the air-pillow transversely on the plate. One disadvantage of the air-pillow was that the position of the patient changed during exposure. He expressed his thanks to the speakers for their kind remarks.

Mr. GUNN read a short paper on the Diagnosis of Renal Calculus, giving briefly the chief symptoms and the relative values of such symptoms in diagnosing renal calculus. Mr. Gunn then discussed the question of how far the opinion of the radiographer should influence the surgeon in his treatment of the patient.—Dr. W. G. HARVEY supplemented Mr. Gunn's paper with a few remarks on the X Ray Diagnosis of Renal Calculi. He agreed with Mr. Gunn that the radiographer should examine the whole urinary tract. In the great majority of cases a negative diagnosis was justified by the absence of a shadow in a sufficiently good negative. Such a negative should show (1) the last ribs; (2) the tips of the transverse processes; (3) the line of the ilio-psoas muscle; and (4) the outline of the lower pole of the kidney. He then showed some lantern slides illustrative of these points.—Dr.

HAUGHTON said that if there was any doubt they should repeat the photograph some time later. But a quicker and more satisfactory way was to take a stereoscopic picture by Mackenzie Davidson's method. It was astonishing how two rather indifferent negatives would yield an excellent stereoscopic result. The question of including the opposite kidney was most important. He had come across patients in which the pain was referred to one side, and there were two large stones in the opposite kidney.—Dr. H. STOKES said they could get the symptoms of stone from a hypernephroma. Most of these were not diagnosed until too late. Cases reported showed the surgeon practically certain of stone. If the radiographer took two photographs and found no stone, were they to sit down and let the patient die?—Mr. PRINGLE and Mr. HAYES also spoke.—Mr. GUNN, in reply, said he did not attempt to deal with the differential diagnosis. What Dr. Stokes said was perfectly true. There were other conditions which made it difficult, but time would not permit their discussion.—Dr. HARVEY also replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Discussion on Blood Pressure.

A MEETING of this society was held on Nov. 30th, Dr. BYROM BRAMWELL, the President, being in the chair.

Dr. GEORGE ALEXANDER GIBSON, in introducing a discussion on Blood Pressure, first gave a definition of the terms employed in studying arterial pressure. The *maximal* or *systolic pressure* was gauged by that which would arrest the flow in the vessel. The *minimal* or *diastolic* pressure was estimated by the point of greatest lateral oscillation. The *mean pressure* was that half-way between maximal and minimal, and the *pulse pressure* was the amount of difference between maximal and minimal. But these pressures were lateral—i.e., exerted on the walls of the vessels—and the *terminal pressure* consisted in this pressure plus the velocity. The lateral pressure in an artery was usually held to be equal to the terminal of the next branch. The $\frac{\text{pulse pressure}}{\text{systolic pressure}}$ = co-efficient of pressure; thus, in a person in health if the systolic pressure were 120, the diastolic 90, the pulse pressure 30, and the pulse-rate 70, then $\frac{\text{P.P.}}{\text{S.P.}}=\frac{30}{120}=\frac{1}{4}$ co-efficient, and $\frac{\text{P.P.} \times \text{P.-rate}}{\text{S.P.} \times \text{pulse-rate}}=\frac{\text{velocity}}{\text{work}}=\frac{30\times70}{120\times70}=\frac{2100}{8400}=\frac{1}{4}$, or the efficiency of the heart in health. In an instance of heart-block S.P. 270, D.P. 90, P.P. 180, P.R. 30, $\frac{180\times30}{270\times30}=\frac{5400}{8100}=\frac{2}{3}$. The factors which maintained the arterial pressure were as follows: 1. Energy of the heart. 2. Access of blood. It had long been known that any obstruction lessened the distal pressure and increased the proximal, and Dr. Gibson narrated an illustrative case of obstruction to the subclavian. 3. Elasticity of the vessels. During the systole the vessels became dilated and the potential energy thus stored up was given out later as kinetic energy in their contraction. 4. Resistance in arterioles; resistance and pressure were reciprocal. Increased resistance was equal to higher pressure, and *vice versâ*. Resistance was due to tonus of vessels which resulted from the antagonistic action of vaso-constrictor and vaso-dilator nerves; the former were always in action, the latter only when required. 5. Character of the blood. Dr. Gibson had observed that density of blood and pressure were in direct ratio, and viscosity of blood stood in the same relation. Chemical impurities, for the most part, increased pressure. 6. Quantity of blood. It might be expected that increased volume would cause increased pressure. This was, however, amply compensated for by vasomotor activity. With regard to the methods of estimating arterial pressure, Dr. Gibson narrated the earliest observations made by ascertaining the height of a column of blood from an artery, and later by the use of a mercury manometer for the artery and a water manometer for the vein; while still more recently the spring manometer had been introduced. The different forms of kymograph were alluded to. He spoke of the early studies of the pulse and the importance of educating the sense of touch in this relation. He said that the only accurate instruments were those based on estimation by means of a column of mercury. The systolic pressure was gauged by the amount of external pressure necessary to overcome arterial resistance; while diastolic pressure was estimated by the maximum waves of the column of mercury. Dr. Gibson described the instruments of Erlanger and the recording instrument suggested by himself. As regarded the possible fallacies in the methods, he alluded to: (1) the instrumental; (2) the personal equation; and (3) the state of the walls—Herringham stated that the maximum pressure exerted by these was 35 millimetres. Dr. William Russell held that increased tonus could add to this, but the muscular coat of a large artery was not so large relatively as a small artery. As to the clinical results, the cardiac muscle and arterial pressure were reciprocal, and arteriole contraction and arterial pressure were also reciprocal. With high arterial pressure there was a loud aortic second sound, going on to hypertrophy; with low pressure there were feeble sounds. Vascular crises (both high and low pressure) of Pal gave changes in the amount of secretion, renal and salivary. Nervous causes lead to high pressure, and worry to this and to sclerosis; while, on the other hand, from high pressure nervous instability in varied forms resulted. Nervous causes could give low pressure, and in the opposite sense low pressure led to nerve depression. Abnormal extremes: In interstitial nephritis and arterial degeneration 260 D.; 300 S. Addisonism, 60 D., 90 S. Greatest pulse pressure in aortic escape, 70 D., 150 S., and in heart-block 80 D., 270 S. In infective diseases there was an early rise and early fall; this was very marked in typhoid fever. In lead poisoning the pressure was high throughout until recovery, and in gouty conditions it was also high. It was interesting to note that, apart from aortic disease, valvular lesions had little influence on pressure. In aortic incompetence the pressure in the arteries of the legs was much higher than in the arteries of the arms. Arterial sclerosis: There was a general consensus of opinion that retained poisons as well as those from outside caused this disease. There might be arterial sclerosis without high pressure, as of 500 cases examined by Groedel in 35 per cent. there was none; Rudolf with Ellis and Robertson found 50 per cent. of cases with none: and D. Elliot Dickson found thick vessels with only moderate pressure in miners. The relation of high pressure to angina pectoris was discussed. Respiratory diseases: The pressure was high in asthma and low in phthisis. Glandular diseases: In myxœdema the pressure was high; in exophthalmic goitre it was usually low, but was very variable. In Addisonism, low if the medullary portion of the gland were affected. Renal disease: The pressure was usually high from retention of poisons, but much depended on previous conditions. In chronic Bright's disease it was always high; in amyloid changes, usually low; in uræmic poisoning, high. In conclusion, Dr. Gibson discussed the value of arterial pressure in prognosis and as a guide in therapeutics.

Dr. WILLIAM RUSSELL said that in the time at his disposal he could not debate the question before the society. He could only try to define what he considered to be the essential phenomena in the subject under consideration. He would begin at the extreme end and take as an example of it a patient admitted to hospital with a brachial pressure of 295 mm. Hg. Under rest and treatment it fell to 165. It rose and kept about 190 to 210, but it would suddenly rise 70 to 80 mm. more with symptoms which there was no time to describe. This patient had thickened vessels, and along with the rise in pressure the vessels, including the brachials, underwent hypertonic contraction.[1] Nine years ago he had made a communication to the society on arterial hypertonus, in which he pointed out that hypertonus occurred in normal and in sclerosed radial arteries; with the advent of the modifications of the Riva Rocci instrument he had carried his observations to the brachial artery and found that it became greatly thickened, and that it could in favourable cases be both felt and seen to diminish greatly in size and increase greatly in the thickness of its wall during such hypertonic contraction. When this contraction took place the pressure in the aorta was raised—how much there was no means of determining, for there was a great power of restoring the balance and relieving the

[1] THE LANCET, Dec. 3rd, 1910, p. 1602.

heart. The essential phenomenon was the arterial hypertonic contraction and that it embraced such vessels as the brachials. His contention was that the hypertonically contracted and sclerosed arterial wall was a large factor in the production of the brachial reading. A source of fallacy occurred from the fact that in some cases a brachial artery, although thickened, was dilated and atonic, and such a vessel gave a relatively lower reading. A man had died in his ward last week who came in with a failing big heart—failing on both sides; the lungs were congested and he began pouring out fluid into both pleuræ, the heart sounds could not be heard, the pulse was a mere flicker at the wrist, the radial arteries were calcareous, the brachials were large, sclerosed, and tortuous, and the brachial pressure during this state of affairs was 140 mm. Hg. In one set of observations he found the pressure in the forearm was 30 millimetres higher than that in the upper arm. At the post-mortem examination the myocardium of the left ventricle was soft and fragmented, and that of the right considerably replaced by fat. Yet eminent clinicians write on blood pressure and heart power, estimated by the hæmomanometer, without a reference to the arterial wall. To him that position was beyond comprehension, and he left it to them as to whether they were prepared to accept it. He would now ask their attention to the other extreme, and could illustrate this by reference to two patients: the one convalescing slowly after an acute pericarditis was quite comfortable with a brachial pressure of 120 millimetres. When from constipation, an error in diet, or emotion the pressure rose 15 or 20 millimetres he got cerebral breathing and the pulse intermitted. When this rise took place the radial and the brachial arteries could be felt to have become smaller from hypertonic contraction—that was not an opinion, that was a clinical fact—the contraction threw an increased pressure into the aorta, and the feeble myocardium was embarrassed. The symptoms could be promptly relieved by giving a vaso-dilator. The second case was a medical friend, aged 80 years, who was having recurring attacks of angina pectoris minor. During these attacks the radials became small and the brachials also became contracted with a very poor wave in them; the pressure showed 140–150 mm. Prompt relief could be obtained by a vaso-dilator, and the pressure fell to 120–125. He found that they entirely overcame this vessel sensitiveness and removed the symptoms by the administration of a very small quantity of iodide of potassium. In both these cases the essential and fundamental clinical phenomenon was the arterial hypertonus, just as it was when the vessels were sclerosed. The constriction might or might not embarrass the heart. No one knew what the pressure was in the aorta; and with the armlet of the hæmomanometer they measured the changes in the arterial wall as well as the pressure inside it.

Dr. HARRY RAINY discussed the physics of the problem. When the pressure was applied by a band to the upper arm the tissues were assumed to be compressed as if they were a fluid, and therefore the constriction was transferred directly to the vessel. This was a point subject to discussion, and it was known that if there was much œdema the facts were admittedly erroneous. There was also the question of the rigidity or relaxation of the muscles. The question of the vascular walls was purely a physical one; a blood-vessel lived for long and experiments could be carried on with it after excision from the body. By perfusing certain fluids through it hypertonus could be set up. The condition of the vessel wall would cause change in pressure. The brachial pressure was a central one, and not far off that observed in the heart, while the pressure became enormously greater the smaller the blood-vessels became. The pressure was really peripheral to those which were investigated—viz., the brachials.

Dr. D. ELLIOT DICKSON (Lochgelly) said that he had investigated this problem in 500 healthy miners of all ages. In 456 there were thickened, easily palpated accessible arteries. In 116 youths under 20 years of age the radial artery was easily palpated, and only 44 miners had such arteries which could not be palpated. Only 31 showed a systolic pressure of over 140 mm., or 6 per cent.; there was no albuminuria. 469, or 94 per cent., had brachial pulse readings within normal limits, and nearly all had thickened arteries. The vessels were equally thickened from the periphery right up to the axilla. They felt like lead pencils and were almost incompressible. He thought that the cause of this thickening might be due to toxic conditions of their work underground. He had observed this thickening of vessels to occur within one year of their commencing underground work. He had determined that in the air of well-ventilated coal mines there was an enormous excess of carbonic acid gas; it might amount to 0·7 per cent., in comparison with the normal 0·03 or 0·04 per cent.

Dr. H. OLIPHANT NICHOLSON spoke of the blood pressure in pregnancy. He said that all the conditions present during the later stages of pregnancy might be thought to favour increased blood pressure, but his observations showed that there was no definite rise of blood pressure until the commencement of labour pains. The uterine contractions raised the pressure, and this rise increased during the expulsion of the child. Operative procedures still further raised the pressure, even though the patient were anæsthetised. After the third stage of labour there was a distinct fall in pressure, but after the third day of the puerperium there was a definite rise. If there were a continuous rise above 130 mm. one might suspect eclampsia. The blood pressure was usually higher in primiparæ than in multiparæ. As a result of pregnancy a vaso-constricting substance was retained in the system and accumulated to a dangerous amount in eclampsia. It caused the albuminuria and suppression of urine by altering the circulation through the kidneys. This substance was probably elaborated from the placenta. Owing to this widespread constriction of the arteriole field much extra work was thrown upon the heart.

Dr. THEODORE SHENNAN said that in thickened arteries which were calcareous a constant feature was present—viz., the absence of this calcareous change at the flexures. At Munich the greatly dilated heart and arterio-sclerosis of vessels so often met with at post-mortem examinations were attributed to the excessive amount of beer drunk. The viscosity of the blood seen in cases of polycythæmia where the heart was not hypertrophied might be due to greatly sclerosed conditions of the coronary arteries.

Dr. EDWIN MATTHEW referred to drugs employed to reduce arterial blood pressure, and said that with the exception of the nitrites and iodides they were useless. It was said that iodides acted by reducing viscosity or that they affected the nutrition of the vessel wall, or that they stimulated thyroid secretion. Iodides were useful in cases of high blood pressure with no arterio-sclerosis, and this was where they found their true action. Iodides were pure vaso-dilators just as nitrites, and acted in no other way. Iodide should be given in minimum doses of 10 grains thrice daily, rapidly increased for some days, and then decreased. It had to be remembered that many organic preparations of iodine contained only 2 grains in each dose.

Dr. HENRY M. CHURCH had found the test for high blood pressure a most useful one as regards therapeutics. The time at which the pressure was taken was important; before breakfast the pressure might be 15 to 20 mm. lower than after, and the same occurred before and after smoking, taking a hot bath, &c.

The PRESIDENT said that he never could understand how it was said that the condition of the vessel wall had no effect on the blood pressure. One might have thickened arterial vessels without any obvious rise in the blood pressure owing to parts of the vessel being left elastic. He had great difficulty in accepting Dr. Russell's view that the brachial and radial arteries from a condition of spasm could give rise to such high readings.

SCOTTISH OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.

Exhibition of Cases.—Double Frontal Sinus Disease.—Purulent Labyrinthitis.

THE first meeting of this new society was held on Nov. 11th at the Royal Infirmary, Edinburgh, under the chairmanship of Dr. A. LOGAN TURNER.

Dr. W. G. PORTER showed a patient two and a half years after Operation on the Right Labyrinth. Granulations were removed from the region of the horizontal canal, but the remaining canals and the cochlea were not interfered with. The vertigo had disappeared and the patient could follow his employment, but complained of severe tinnitus. It was a

question for discussion whether any further surgical treatment should be carried out.—Dr. J. KERR LOVE and Dr. THOMAS BARR advised against this, and Dr. J. M. FARQUHARSON suggested the use of the high-frequency current and injections of fibrolysin.

Dr. PORTER reported the case of a patient with Clonic Spasm of the Right Vocal Cord and Soft Palate. The movement of the cord consisted of a rapid adduction and a slower abduction, and the rate was about 150 a minute. It was thought that the phenomenon was due to bilateral cerebral disease probably associated with arterio-sclerosis. The patient died suddenly, but no post-mortem examination was obtained.

Dr. J. D. LITHGOW read notes of a case of Double Frontal Sinus Disease with cerebral involvement. There was a deficiency of the cerebral wall of the right sinus and through this a fungating mass of necrotic cerebral tissue presented. Operation resulted in recovery.

Dr. J. S. FRASER reported a somewhat similar case which, however, ended fatally. In this patient the frontal sinus suppuration was complicated by extra- and intra-dural abscesses in the frontal region.—Dr. W. S. SYME, in the discussion, remarked on the increasing frequency with which reports of intracranial complications of frontal sinus disease were being published, and pointed out that in reference to the question of operation on the sinus this danger must be taken into account.—Dr. TURNER stated that, besides these two cases, one other, making three within the year, had occurred in the Edinburgh Royal Infirmary, and he drew attention to the statistics of Gerber, who has collected 150 cases of intracranial disease following suppuration in one or other of the nasal accessory cavities.

Dr. FRASER read notes of a case of Purulent Labyrinthitis with death from lepto-meningitis and gave a lantern demonstration. This showed the condition after operation. The vestibule was efficiently drained, but pus was present in all the coils of the cochlea, especially in the scala tympani, in the ductus endolymphaticus, and in the ductus perilymphaticus. The inflammatory process could also be traced to the internal auditory meatus from the scalæ of the cochlea along the branches of the cochlear nerve.—A discussion took place, in which Dr. T. BARR, Dr. KERR LOVE, and Dr. ALBERT A. GRAY took part, as to the indications for opening the internal ear spaces, the general opinion being that there was a tendency at present to too hasty interference with the labyrinth in aural suppuration.

Dr. FRASER showed a patient on whom Killian's operation had been performed for Unilateral Frontal Sinus Disease.

Dr. J. MALCOLM FARQUHARSON showed a patient presenting symptoms of Cerebro-spinal Rhinorrhœa. The condition followed a severe fall on the back of the head. There was a clear watery discharge from the right nostril presenting the characteristics and conforming to the tests of cerebro-spinal fluid. The patient suffered from severe headaches before the nasal discharge commenced. There was now complete double optic atrophy, and on the right side deafness of nerve type. The nasal passages were narrow but otherwise healthy.—In the discussion Dr. TURNER suggested the presence of an intracranial tumour and recommended that the patient should be examined by a neurologist, and Dr. SYME advised the performance of spinal puncture.

Dr. FARQUHARSON also showed: 1. A young woman who had sudden attacks of Angio-neurotic Paralysis of the Right Acoustic Nerve, associated with vertigo, deafness, severe tinnitus, pallor of the face, and nausea. Complete recovery followed in a few minutes. On examination the ear was normal. Under treatment by X rays and electric current to the sympathetic in the neck, with injections of 1 in 1000 adrenalin, the attacks had become less frequent and severe. 2. A patient on whom Rougé's operation had been performed to permit of the treatment of extensive Lupus of the Nasal Cavity. 3. A man with a large Epitheliomatous Growth of the Pharynx in whom treatment by X rays and radium had resulted in retardation and diminution of the growth with relief of pain, with, however, succeeding rapid extension. 4. A patient with a large Choanal Polypus on the left side. By posterior rhinoscopy its attachment to the posterior part of the middle meatus could be seen. (Dr. A. BROWN KELLY offered some observations on the relation of these polypi to the antral cavity.) 5. A patient with a Papilloma attached to the anterior third of the left vocal cord. 6. A man with Congenital Malformation of the Larynx. The left arytenoid prominence was much smaller than the right, probably from an absence of the accessory cartilages. The patient came to the hospital for some trouble unconnected with the larynx. The movements of the cord and the voice were normal.

Dr. TURNER showed a female with a large, tense, freely moveable Swelling in the Floor of the Left Nostril just inside the ala. A diagnosis of retention cyst of one of the mucous glands was made.—Dr. KELLY, Dr. R. FULLERTON, and Dr. FRASER agreed with this, and the first referred to a number of similar cases which he had seen, remarking on the much greater frequency with which, from his experience, they occurred in females than in males.

Dr. TURNER also showed: 1. A case of Laryngeal Tuberculosis in which an 85 per cent. solution of alcohol had been injected into the right superior laryngeal nerve for the relief of dysphagia. The patient had had two injections at an interval of three weeks with relief of the pain, especially since the latter injection. Unfortunately, the disease had extended to the left side so that the relief was only partial. (Dr. H. PETERKIN made some observations on this method of treatment.) 2 and 3. Two cases of Acute Lepto-meningitis complicating chronic middle-ear suppuration; recovery. One, a male aged 16 years, had had left middle-ear suppuration for years. A week before admission he was seized with acute symptoms, vomiting, headache, vertigo, and elevation of temperature. Lumbar puncture showed the cerebro-spinal fluid under pressure, slightly turbid, with excess of albumin. A radical mastoid operation was done, but no evidence of inner ear disease was found. Two days later he had rigidity of the neck, double Kernig's sign, severe headache, and high temperature, but no optic neuritis. A second lumbar puncture was done, and from the fluid withdrawn streptococcus pyogenes, bacillus proteus, and a Gram-positive anaerobe were grown, and the same organisms were found in the discharge from the mastoid. Antistreptococcic serum was injected into the spinal canal on two occasions, and subcutaneously on five, and spinal puncture was subsequently performed. At the end of three weeks all the symptoms had disappeared. The second case, a male aged 29 years, was somewhat similar except that in him in the left, the diseased ear, there was evidence of vestibular impairment, the caloric reaction being negative, and there was spontaneous nystagmus towards the healthy side. The cochlear nerve remained active. Symptoms of meningitis showed themselves, but there was no optic neuritis. Lumbar puncture showed fluid under pressure and turbid, containing polymorphonuclear leucocytes, lymphocytes, and degenerated epithelial cells. A radical mastoid operation was performed and a cholesteatoma evacuated. Openings were found in the external semicircular canal and in the oval window, discharging dirty fluid. Drainage was established. A second lumbar puncture showed Gram-positive and Gram-negative bacilli and Gram-positive cocci. The mastoid and inner ear secretion showed streptococcus pyogenes and a diphtheroid bacillus. Lumbar puncture was performed on several occasions and antistreptococcic serum was injected into the spinal canal and subcutaneously. Gradual improvement and ultimate recovery resulted.—Dr. J. STODDART BARR and Dr. SYME discussed these two cases.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held at the Sussex County Hospital on Nov. 23rd, Dr. F. Hinds being in the chair.—Dr. W. Broadbent showed a case of Aneurysm in a woman. There was no history of syphilis, but she had been nursing a very stout lady for two years, which involved heavy lifting. She came complaining of cough, hoarseness, and pain in the chest. There was no difference between the pulses and the pupils were equal. There was perceptible pulsation in the first and second left spaces for 2½ inches to the left of the sternum, and this area was dull on percussion. There was a loud booming second sound characteristic of aneurysm, more marked in the first space, and heard even beyond the mid-clavicular line. At the aortic cartilage the second sound was loud and somewhat altered in pitch. The breath sounds were a little diminished on the left side owing to pressure on the left bronchus. There had been very numerous crepitations in the left lower lobe, probably caused by obstruction to the pulmonary vein. The left vocal cord was paralysed. The prognosis was bad owing to the structures pressed upon.—Dr. Broadbent also showed a case of Progressive Muscular Atrophy in a woman, and a case of Aortic Regurgitation in a man aged 24 years.—Mr. H.

Nethersole Fletcher showed a boy, aged 11 years, with a Swelling on the Lower Part of the Tibia. Four months ago he first noticed this just above the left ankle, which had gradually increased in size. There was no pain and no limping. The swelling was hard, slightly nodular and bossy, and not tender. It measured about 1½ inches each way. X rays showed that it arose from the region of the epiphyseal line of the tibia, and that it was in the main composed of fully formed bone lamellæ continuous with those of the cancellous tissue of the shaft of the tibia. The outer surface was capped with dense bone about a quarter of an inch thick. The fibula was directly pressed upon it, and over the area of pressure had been bowed outward and partly absorbed. It was probably a cancellous osteoma or a chondroma which had ossified growing from the epiphyseal line.—Dr. J. F. Gordon Dill showed a series of cases of Glycosuria in which a careful estimate had been arrived at of the amount of carbohydrates which each individual patient was capable of assimilating, and in which a reduction in the diet to this amount had been followed by a disappearance of the diabetic symptoms and of the sugar in the urine. He also showed a case in which there had been continual fever for four weeks with a positive Widal reaction in which after removal of some carious teeth the temperature became and continued to be normal and the patient recovered perfectly.—Dr. E. Hobhouse showed three cases of Paraplegia of different type. 1. A girl, aged 12 years, was admitted for a large abscess under the chin following impetigo. A sudden illness developed in hospital, with high fever, vomiting, and complete paraplegia in 24 hours. This was followed 48 hours later by loss of vision in one eye and 24 hours after in the other. The outline of both discs was blurred, but there was no definite neuritis. After three months the motor and sphincter paralysis was still complete and sensation greatly impaired, and all reflexes were absent, both superficial and deep. Both optic discs were pale, with clearly defined margins, but vision had greatly improved and she could read large print. Diagnosis: Myelitis of septic origin, involving the lumbar enlargement, and post-papillitic neuritis followed by atrophy, a very rare complication. 2. Paraplegia of the ordinary type in a female, aged 22 years. The onset was irregular, without fever. Diagnosis: Transverse dorsal myelitis (? specific). 3. A man, aged 22 years. Onset acute, with fever, headache, and vomiting. This was followed in from 12 to 24 hours by loss of power in the leg, not complete, and affecting some groups of muscles more than others—e.g., the extensors of the thigh and the peronei. Wasting was rather rapid and the response to the faradic current lessened, being about equal to that of the constant current. The sphincters were unaffected and sensation was normal. The knee-jerk was abolished, there was no ankle clonus, and the other reflexes were normal. Diagnosis: anterior poliomyelitis in the adult of the paraplegic type. Dr. Hobhouse also showed a case of the spleno-myelogenous variety of Leucocythæmia in a female, aged 40 years, of two or three years' duration. The remarkable feature in this case was the sudden drop in the number of leucocytes from 173,000 to 6000 and subsequently to 1600, with a complete alteration in the blood picture. The myelocytes dropped from 22·0 to 2·0, whilst the mast cells increased in about the same proportion, small lymphocytes also rising from 7·5 to 26. The general condition of the patient improved considerably, but there was little, if any, alteration in the size of the spleen, which filled half the abdomen. The treatment was first the injection of soamin three times weekly, which at the time seemed to have no effect, followed by the administration of liquor arsenicalis in increasing doses till 10 minims three times daily were being given. This was discontinued on the progressive fall of the leucocytes and iron substitu'ed.—Dr. Donald G. Hall showed a case of Leontiasis Ossea in a woman aged 72 years. The characteristic changes were present in the bones of the face, and the new bone had invaded the nasal and oral cavities. The patient also showed great thickening of the femora, tibiæ, and fibulæ. The probable pathology in this case was a progressive osteitis due to tertiary specific disease. Photographs and skiagrams of this patient were shown. Dr. Hall also showed a man, aged 46 years, suffering from Pulmonary Osteo-arthropathy, secondary to bronchiectasis of long standing, and two cases of Insular Sclerosis, the first in a man, aged 32 years, with a two years' history of difficulty in walking. This patient had temporarily improved to a marked extent. The second example was in a woman, aged 32 years, with a history of six years' duration, and exhibiting all the symptoms of the disease in a much more advanced stage.—Dr. C. F. Bailey showed a case of well-marked Keloid of the Face and Hand following burns.—The following specimens were exhibited.—Dr. Dill: A Stomach showing a large Malignant Ulcer, which had perforated a vessel causing profuse melæna.—Mr. R. F. Jowers: A specimen of Twisted Ovarian Cyst from a child aged 10 years, which had given rise to symptoms simulating appendicitis. He also showed a Gall-bladder which he had removed for primary carcinoma.—Dr. Hobhouse: A Blood Film from a case of Spleno-medullary Leukæmia, showing polymorphs, myelocytes, and mast cells; also a Liver from a case of Cirrhosis in a girl aged 20 years. The liver was embedded in a mass of adhesions of peri-hepatitis. There was multi-lobular cirrhosis and very little normal liver tissue. A microscopic specimen of the same was exhibited.—Mr. Fletcher: A specimen from a case of Malignant Ulcer of the Stomach, spreading from the duodenum for one and a half inches and causing no symptoms; also a specimen of Sarcoma of the Penis, with microscopic slides of the same and of the secondary growths in the glands. It was a mixed spindle and round cell growth, originating in the corpus cavernosum, and was covered by normal epithelium.—Dr. E. F. Maynard: A photograph and specimen of a Glandular Mass from a case of Lymphadenoma.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 25th, Dr. W. H. Cheetham being in the chair.—Dr. W. H. Maxwell Telling read a paper on Nodular Fibro-myositis, and pointed out its identity with so-called chronic muscular rheumatism, the underlying pathology of which was an inflammatory hyperplasia of the fibrous tissues with a certain amount of exudation. He drew attention to the neglect of this condition by English authors and insisted that the only curative treatment of these cases was massage. He quoted a number of cases which illustrated both the severity and protean manifestations of the disease as well as its amenability to treatment by massage properly and skilfully applied.—Mr. J. Stewart showed a specimen of Inverted Meckel's Diverticulum from a child, aged 5½ years, who was seen at the end of 78 hours suffering from signs of intussusception. On opening the abdomen gangrenous-smelling fluid escaped in large quantity. There was an enteric intussusception, which by coaxing was reduced with the exception of a small truncated mass inside the gut. This was seen to be a Meckel's diverticulum. An incision was made in the gut below this; it was drawn through the incision, tied and cut off, and the wound closed. The child died.—Dr. C. Oldfield showed a Fibroid Tumour of the Uterus of unusual appearance. It looked like adipocere; under the microscope the muscle outlines and nuclei could be seen, but staining was faint. Oöphorectomy had been done 17 years before; this did not relieve other symptoms than menorrhagia and distressing pain, and urinary symptoms had called for radical treatment. No change in the size of the tumour resulted from this oöphorectomy.—Mr. W. Thompson showed a Calculus removed from the Left Ureter at the back of the Iliac Crest. A plum stone was removed from the colon which was temporarily mistaken for the calculus in the ureter.—Mr. B. G. A. Moynihan showed a series of specimens from a case of Cholecystectomy, three of which illustrated a difficulty and a danger in the operation. In these three a portion of the hepatic duct had been removed with the gall-bladder. It was shown by reference to the specimens that a distortion of a distended hepatic duct might result from the cicatricial contraction of a gall-bladder, the seat of repeated inflammation. The gall-bladder became then broadly sessile, and in its pedicle the hepatic duct was drawn up. The defect could be remedied by suture over a catheter pushed upwards from the common duct.—Mr. J. F. Dobson showed a specimen of Meckel's Diverticulum and Peritonitis, with resection of the diverticulum, drainage, and recovery.—Dr. Telling showed a Factitious Dermatitis in a girl aged 18 years. By rubbing with a wet finger she had produced oval lesions about 1 inch to 1½ inches looking like patches of ordinary moist eczema. The distribution of these extended from below Poupart's ligament to the

dorsa of the feet and was on the anterior surface of the limbs. There were no other lesions. The first lesion appeared three months before. Since that date there had been one or two fresh lesions regularly every day, and the lesions were almost identical in size and shape and practically equidistant from each other. No treatment was adopted, the girl admitting that they were self-inflicted.—Cases and specimens were also shown by Mr. E. Hawkesworth Hackett, Dr. Alexander Sharp, Mr. H. Littlewood, Dr. T. Wardrop Griffith, Mr. G. Constable Hayes, Mr. H. L. Flint, Dr. J. B. Hellier, and Mr. Stewart.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Nov. 24th, Dr. M. Handfield-Jones, the President, being in the chair.—Dr. Sidney P. Phillips read a paper on Fevers from the Standpoint of the Clinician. Dr. Phillips drew attention to the declining mortality from infectious fevers as evidenced by the Registrar-General's returns, and pointed out that this was partly due to a decreased incidence of these diseases and partly to a decreased case mortality. Speaking of rötheln, he considered there were many cases in which the rash did not appear before the third day, and gave details of cases in his practice in which feverish symptoms of an influenzal type had been present for a few days before the rash. In the differential diagnosis between this complaint and measles he laid stress on the value of Koplik's spots. He had known cases of measles being mistaken for small-pox owing to the shotty feeling of the rash when it first appeared on the forehead. He had also seen pityriasis rubra accompanied by fever simulating the rash of measles. Amongst the sequelæ of the affection he drew special attention to tuberculous peritonitis. In speaking of mumps he read notes of some very severe cases in which maniacal symptoms obscured the diagnosis; the testicle was generally affected in these cases. He advised mercury in the treatment of mumps owing to its well-known influence on the salivary glands. Typhoid was one of the fevers in which there had been a decline in the mortality, but in this case mainly due to diminished incidence, the case mortality remaining about the same. He recommended whey and citrated milk; the latter, however, did not prevent thrombosis as a sequela, contrary to his expectation. He gave small doses of calomel as an intestinal disinfectant; it was not contra-indicated by diarrhœa or melæna; he recommended sanitas enemata and thought cold bathing impracticable in private practice. He had seen several cases of typhoid fever complicated by pregnancy; in the early months they generally aborted, in the later went to full time. Speaking generally, he considered that hyperpyrexia as a complication of fevers was always due to some local cause such as pneumonia, rheumatic fever, and in typhoid fever, perforation, and such causes should always be sought for. The combination of two exanthems in the same patient was no uncommon occurrence in the fever hospitals, however rare it might be in private. The following took part in the discussion:—Dr. T. Hartigan; Dr. C. O. Fowler, who thought that the cases of rötheln in which rash appeared on the third day might be cases of influenza accompanied by rash—he also laid stress on the importance, where cold bathing was adopted in typhoid fever, of thoroughly skilful lifting of the patient into and out of the bath; Sir John Broadbent, who mentioned cases illustrating the non-infectivity of the pre-eruptive stage of scarlet fever and also advocated the calomel treatment of typhoid fever; and Dr. G. de B. Turtle, Dr. E. Graham Little, and Mr. Albert Kisch.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 24th, Dr. T. R. Bradshaw, the President, being in the chair.—Mr. K. W. Monsarrat showed a patient suffering from Osteitis Deformans. The patient was 40 years of age and a photograph taken at about the age of 21 showed that he was then quite free from any disease of the bones. The bones of the legs were markedly thickened and bent outwards, and there was a similar deformity in the bones of the forearms. There had been progressive enlargement of the head and there was a prominent median boss over the frontal and parietal bones. The right clavicle was greatly thickened. Several fractures had occurred after slight injuries.—Dr. R. M. Manwaring-White mentioned a similar case which had recently been under his care.—The President suggested the possibility of late rickets.—Mr. R. E. Kelly briefly described Mayo's operation for Hallux Valgus. He showed that the condition was essentially one of a long great-toe, and necessitated the removal of a large portion of the head of the metatarsal bone so as to reduce it in length. He then described the ingenious use of the bunion or adventitious bursa in forming a new joint. The case was illustrated by X ray photographs of the foot.—Mr. T. R. W. Armour alluded to the great danger of sepsis in the bursa, and said that he had had many successes with the older methods of operation.—Mr. G. P. Newbolt also spoke in a similar sense, and laid stress upon the importance in some cases of dividing the tendon of the extensor hallucis.—Dr. A. A. Bradburne read a paper on Incipient Glaucoma, its Diagnosis and Treatment. He laid the greatest stress upon the importance of the diagnosis in the earliest possible stage, and discussed in detail the ophthalmoscopic signs. He considered its division into primary and secondary forms, and pointed out that the recognition of the disease depended upon a knowledge of the effects of hypertension; he then considered the effects of this upon the several parts of the eye and described the objective signs. Mr. Bradburne mentioned the difficulties of treatment, the great importance of medical and preventive treatment, and described a modification of the ordinary iridectomy which he was in the habit of performing, which consisted in drawing a small part of the iris forwards and inwards before detaching it.—Mr. A. Nimmo Walker considered Priestley Smith's modification of Bjerrum's test for incipient glaucoma to be of value, and he now used it in his routine examination of patients. He was experimenting with Schioetz's tonometer, which he thought had come to stay, as it was more scientific and trustworthy than digital palpation. In regard to operative measures, he did not do iridectomy, which in his opinion was unnecessary and often useless; in acute cases he did cyclotomy, and in chronic cases sclero-corneal trephining, although his experience of this operation was comparatively small. The results, as far as they went, were encouraging.—Dr. K. A. Grossmann said that the symptoms could not be considered as pathognomonic when they occurred alone. He instanced a case where, with an apparently marked glaucomatous cup, the vision was normal as regards colour, form, and field. He maintained that the cause of glaucoma was not yet found. Of operative methods the iridectomy proposed by Graefe 60 years ago still was the best, though no one could explain why it was beneficial. He advocated this operation with a wide basal incision.—Mr. T. H. Bickerton alluded to the great difficulty there might be in deciding upon the proper treatment in a given case.

MANCHESTER DERMATOLOGICAL SOCIETY.—At a meeting held on Nov. 12th in the Manchester and Salford Hospital for Diseases of the Skin, all the members of the staff being present, it was unanimously decided to form a Dermatological Society in Manchester.—Dr. H. A. G. Brooke was elected President of the society and Dr. William Dyson honorary secretary.—Dr. R. B. Wild showed: (1) Hyperidrosis of the Forearm following a Fracture; (2) two cases of Tuberculous Lymphangitis; (3) an anamolous case of Pityriasis Rubra Pilaris with Ichthyosis; and (4) Morphœa.—Dr. G. H. Lancashire showed: (1) Lupus Vulgaris simulating Lupus Erythematosus; (2) Papular Eruption of the Neck of a man aged 24 years (for diagnosis); (3) Tuberculous Ulceration of the Upper Lip; and (4) Lupus Vulgaris, discrete nodules scattered over the face, with marked erythema and œdema.—Mr. L. Savatard showed: (1) Multiple Fibro-neuromata, with thickened cutaneous nerves; (2) Papular Tuberculide of the Face, which had cleared up after an attack of erysipelas; and (3) an extensive case of Lupus Vulgaris, which had remained well for several years.

COLONIAL MEDICAL SERVICE: WEST AFRICAN MEDICAL STAFF.—Mr. W. S. Snell, medical officer, Southern Nigeria, has retired from the service, and Dr. F. M. Simmonds, medical officer, Gold Coast, has resigned with a gratuity. Mr. W. H. G. H. Best and Dr. C. R. Chichester, senior medical officers, Southern Nigeria, have been promoted to Provincial Medical Officers. Mr. H. C. Jeffreys, formerly a medical officer in British Honduras, has been selected for appointment to the Staff and posted temporarily to Sierra Leone.

Reviews and Notices of Books.

Die Wassermannsche Reaktion, mit besonderer Berücksichtigung ihrer klinischen Verwertbarkeit. (Wassermann's Reaction, with Special Consideration of its Clinical Application.) Von Priv.-Doz. Dr. HARALD BOAS, I. Assistenten am Rudolf Berghs-Hospital für venerischen Krankheiten in Kopenhagen. Mit einem Vorwort von Geh.-Rat. Professor Dr. A. WASSERMANN. Berlin: S. Karger. Pp. 186. Price, paper, 5.60 marks; bound, 6.80 marks.

THE striking results of research upon the cause, diagnosis, and treatment of syphilis during the past five years when considered together afford one of the most notable instances of the rapid advances yielded to practical medicine by the application of scientific experimental methods. The successful inoculation of the disease upon apes by Metchnikoff and Roux in 1903, the discovery of the spirochæta pallida by Schaudinn and Hoffman in 1905, the evolution of Wassermann's serum test in 1906, and the remarkable work upon the treatment of the disease by Ehrlich and Hata during the present year by means of dioxydiamidoarsenobenzol, or "606," form a series of epoch-marking advances which are fresh in the minds of all. These observations are to some extent interdependent and complementary, which no doubt partly accounts for the great rapidity with which they have followed one another. Although there are many details which are yet obscure and require further investigations, systematic and laborious in nature, for their elucidation, it is perhaps not too much to hope that the final outcome will be to remove the diagnosis and treatment of syphilis from the realms of speculation and empiricism and to place them upon an assured scientific basis.

The diagnostic serum reaction, which is now generally known as Wassermann's reaction, was first published in the *Deutsche Medizinische Wochenschrift* of May 10th, 1906, by Wassermann, Neisser, and Bruck. It is in principle an application of the general phenomenon of deviation or fixation of complement first described by Bordet and Gengou in 1901, a fact which is perhaps less generally known than it should be. Since its first introduction Wassermann's reaction has been the subject of a very large number of researches by workers all over the world, and it has been modified in various ways, some of these modifications showing very marked differences from the original method. Consequently the literature of this subject alone is very considerable, and the statement that a given individual is the subject of a positive Wassermann reaction is often one that requires amplification before its exact value can be appraised, since the different modifications yield results of varying degrees of specificity as judged by the statistics of those employing them. A critical and authoritative consideration of the whole question is therefore desirable. This is afforded in the book before us, which has a highly commendatory preface written by Professor Wassermann himself, stating that the conclusions arrived at by Dr. Boas are in complete accord with the observations made in Professor Wassermann's own laboratory.

Dr. Boas first gives an interesting historical review of the observations upon this subject up to the present time, and explains very clearly the general principles of the method. He describes the modifications which have been introduced, and reviews the chief results obtained by various observers, referring briefly to some of the chief explanations offered of the phenomena. The technique of the reaction is then very carefully and fully described. The essentials, as in any instance of the Bordet-Gengou reaction, are an amboceptor, complement, blood corpuscles, antigen, and the serum of the patient. The first three comprise what is now generally known as a hæmolytic system, and the last two are the factors which serve to deviate or fix the complement, thus preventing hæmolysis and affording the visible basis of the reaction. The amboceptor used by Wassermann and also by Boas is the serum of a rabbit immunised for sheep's corpuscles, and inactivated by warming to 56° C. for half an hour. For complement fresh guinea-pig's serum is employed. The blood corpuscles used in the test are those of the sheep in a 5 per cent. dilution. The original antigen used by Wassermann and his co-workers was an extract of some syphilitic organ. The antigen generally employed by Dr. Boas has been an alcoholic extract of human heart, not necessarily from a syphilitic person, since it has been repeatedly shown that other substances than syphilitic extracts, such as lecithin, sodium taurocholate, &c., can act as effective antigens. The serum from the patient is derived from blood drawn from the ear or from a small vein. This should not be done in direct sunlight, and the serum should be inactivated as soon as possible by heating to 56° C. for half an hour. The mode of carrying out the reaction, including the titration of the amboceptor and of the complement, the preparation of the various dilutions and of the necessary controls, is described most clearly, and a method of quantitative recording of the results is outlined. Some of the numerous modifications of and substitutes for Wassermann's reaction are referred to, and Dr. Boas comes to the conclusion that the original reaction is the most satisfactory.

In order to appraise the value of the reaction Dr. Boas has carried out a large number of control observations upon diseases other than syphilis, especially upon those in which it has been affirmed by other observers that a positive reaction occurs. In scarlet fever it was stated by Much and Eichelberg that a positive reaction was found in 10 out of 25 cases. Dr. Boas finds that the reaction is occasionally present but that it is very transitory, and that its occurrence does not lessen the value of Wassermann's reaction. In cases of pulmonary tuberculosis, pneumonia, malignant growths, typhoid fever, and diabetes mellitus, in all of which a positive reaction has been described by other investigators, Dr. Boas obtained almost invariably negative results. In malaria positive reactions occasionally occur, in leprosy the tuberculous form often gives a positive reaction, the anæsthetic form but rarely does so. Similar positive reactions have been described in framboesia and in relapsing fever. Dr. Boas records 1064 control observations on normal individuals and on cases of other diseases than syphilis, and of these only one case—one of scarlet fever—gave a positive reaction. He therefore concludes that in countries other than tropical ones Wassermann's reaction is specific for syphilis.

A careful analysis of the significance in regard to diagnosis and treatment of a positive Wassermann reaction in cases of syphilis and of the various parasyphilitic conditions is given by Dr. Boas. With a doubtful primary sore, an absence of the reaction is not a proof of its being non-syphilitic, nor is a positive reaction indicative of anything more than that the patient is the subject of syphilis. In the secondary stage, the positive reaction is constant in cases which have not been treated, but it may be wanting occasionally in fresh outbreaks of secondary symptoms in cases which have been under treatment. Similar statements are made in regard to the tertiary stage, and in general it is maintained that the reaction is far more marked in cases which have not been treated than in those that have. In regard to latent syphilis, only a positive reaction can be taken as possessing any diagnostic value. It is stated that the occurrence of a positive reaction after treatment is an indication that a recurrence of symptoms will speedily occur, or, as Professor Wassermann

expresses it in the preface, a persistent positive reaction in a syphilitic person indicates the presence of spirochætæ in his organism. In general paralysis of the insane a positive reaction with the serum occurred constantly; it was also obtained with the cerebro-spinal fluid in 91 per cent. of the cases investigated. In tabes dorsalis all cases previously untreated by antisyphilitic drugs gave a positive reaction. Dr. Boas is careful to urge caution in the interpretation of a negative reaction, both in regard to diagnosis and prognosis of syphilis. He claims that the reaction is a valuable addition to our means of studying syphilis, and he suggests that it will find useful applications in forensic medicine, in the examination of wet-nurses, and in the investigation of candidates for life assurance who have had syphilis. This book affords an admirable analysis of the practical results of Wassermann's reaction, and, being furnished with a very extensive bibliography, should be of value both to bacteriologists and clinicians.

Spondylo-therapy: Spinal Concussion and the Application of Other Methods to the Spine in the Treatment of Disease. By ALBERT ABRAMS, A.M., M.D. Heidelberg, Consulting Physician to the Mount Zion and French Hospitals, San Francisco. Illustrated. San Francisco: The Philopolis Press. 1910. Pp. 400. Price $3 50.

A QUOTATION from the author's preface is the readiest way of expressing the point of view of this book. "The subject of spinal therapeutics has received less attention from the medical profession than it deserves. Even the laity know that cold applied to the back of the neck may arrest hæmorrhage from the nose, and that heat applied to the small of the back may hasten menstruation. The profound and far-reaching physiologic truths which underlie these simple phenomena have either been ignored or only given inconsiderate attention. ..... One of the author's truest motives has been to lift this whole subject of spinal therapy out of the low state in which it blunders onward, hitting or missing as the case may be, and rescuing it from the lowly esteem which physicians as a class have thus felt for it. He has endeavoured to put it in a place befitting its scientific importance, and to emphasise its great practical helpfulness in disease."

After a brief historical retrospect and an anatomical and physiological introduction, the author proceeds to discuss the subjective and objective symptomatology of affections of the back and to give a summary (by no means comprehensive) of spinal diseases and symptoms, from "litigation back" to "vertebral insufficiency." He then passes on to general spondylo-therapy, which includes acupuncture, counter-irritation, electro-therapy, exercises, hydro-therapy, psychro-therapy (freezing), thermo-therapy, and vibratory massage. Some of these are, in the author's opinion, much more serviceable than others; he assigns paramount importance to percussion, sinusoidalisation, and psychro-therapy.

Even allowing for the venial enthusiasm of the specialist, we admit a sense of astonishment, if not of bewilderment, at some of the author's methods and apparent results. His contention is, in a word, that certain "vertebral reflexes" can be elicited by tapping various vertebral spines. These "reflexes" consist in modification of the form and position and secondarily of the function of certain of the viscera, such as the heart, lungs, spleen, intestines, aorta, and bronchi. In addition, however, certain cutaneous and muscular phenomena can be produced by similar methods. When, then, we suspect disease, functional or organic, of any particular viscus or viscera, or of any system such as the vaso-motor, or when we are confronted with any sort of pain or neuralgia or paræsthesia, we must seek out the corresponding spinal segment or segments, thence the corresponding "spinal window" (point of exit of spinal root), and attempt to influence the latter by percussion, freezing, or sinusoidalisation. For erythromelalgia, acrodynia, aortic aneurysm, migraine, exophthalmic goitre, diabetes mellitus, coryza, cold extremities, vaso-motor symptoms of the neuroses, vascular hypertension, and certain toxic conditions—this is the author's inclusive list—he taps the spine of the seventh cervical vertebra. For asthma he applies the sinusoidal current over the fourth and fifth cervical vertebræ; for vascular hypotension, the four lowest dorsal vertebræ; for nervous diarrhœa, peristaltic unrest, entero-spasm, constipation, and meteorism, the eleventh dorsal spine; for hepatic toxæmia, the first three lumbar spines, and so on.

Some of the clinical records supplied by the author are startling enough and border on the incredible; for while the rationale of the method can be appreciated within certain limits, both experimental and clinical corroboration is required of much that is stated baldly if not tacitly assumed. Dr. Abrams frankly allows that his book is a pioneer effort and asks that it be judged as such.

American Practice of Surgery: A Complete System of the Science and Art of Surgery by Representative Surgeons of the United States and Canada. Editors: JOSEPH D. BRYANT, M.D., LL.D., and ALBERT H. BUCK, M.D., of New York City. Complete in eight vols. Profusely illustrated. Vol. VII. New York: William Wood and Company. Pp. 761. Price $7 per volume.

THE appearance of the seventh volume tells us that this great System of Surgery is drawing to a close. It contains much that is of interest, especially as it deals in great part with the surgery of the abdomen. The first section is by Dr. C. H. Peck of New York City, and treats of the surgical conditions of the pelvic and gluteal regions. In this the most important subject dealt with is the congenital sacro-coccygeal tumour. In a chapter entitled "Surgical Diseases of the Extremities" Dr. C. A. Porter and Dr. William C. Quinby of Boston, Massachusetts, have described those minor disorders which do not naturally fall into any of the other chapters of the work. Thus we find an account of X ray dermatitis, ingrowing toenail, subacromial bursitis, paronychia, and many similar affections. These are just the conditions which so often are omitted in elaborate treatises on surgery, and we are glad to see they have been dealt with adequately here. It is a useful chapter, and we agree with the treatment advised. On one point we should like an explanation. For hæmatoma of the quadriceps femoris the following treatment is given: "The patient should be kept at rest in bed for the first few days, and baking and moderate bandaging should be employed." We do not understand what is meant by "baking."

Surgical diseases and wounds of the abdominal wall have been dealt with by Dr. J. D. Griffith of Kansas City, who contributes an interesting account of desmoids of the abdominal wall, illustrated by two excellent coloured plates. In a chapter on the diagnosis of tumours of the abdomen Dr. Malcolm L. S. Harris, of Chicago, has described, as fully as the few pages allotted to him will allow, this difficult subject, but we think it would have been well to have allotted more space to it. In a chapter on abdominal section, by Dr. W. M. Mastin of Mobile, Alabama, the author discusses the site of incision and the mode in which incisions should be made. The question of drainage is also considered and the objections are mentioned, but we think that hardly sufficient stress is laid on the risks of the drain forming a channel by which the peritoneum may become infected. Some useful instructions are given for

the preparation of the patient for the operation and for the after-treatment.

The very important modern subject of the surgery of the pericardium and heart has been dealt with by Dr. R. G. Le Conte and Dr. F. T. Stewart of Philadelphia. The anatomical considerations are described; the authors recommend that the safest point for puncturing the pericardium is the fifth interspace close to the left edge of the sternum; they describe many of the incisions which have been recommended for exposing the heart and in discussing the relative merits of these they maintain that no definite plan can be laid down for all cases. The situation of the wound, the condition of the pleural cavity, and the degree of certainty of the diagnosis must influence the incision made. The subject of the arrest of hæmorrhage is fully considered. The suture of arteries and their anastomoses are also well described, and in the same chapter we find an account of the treatment of aneurysm.

Dr. A. J. Ochsner of Chicago has written on the surgical diseases of the stomach and œsophagus. The section occupies more than 100 pages and is almost a treatise by itself. The various methods of performing gastro-enterostomy and gastrostomy are described; the account is well illustrated, and a good description is given of the surgery of the œsophagus, but we cannot help thinking that some of the methods of dilating strictures of the œsophagus which are described are hardly worth the space allotted to them. Although many of them are exceedingly ingenious, the cases in which they are applicable are very few, and their value has yet to be proved. Dr. J. Charles Reeve, junior, of Dayton, Ohio, has contributed the section on the surgery of the diaphragm and subphrenic abscess. It is seldom that these subjects are described so thoroughly as here; the importance of subphrenic abscess is very great, and we are pleased to see that it receives this degree of attention.
